INDEX

NAME INDEX

Abbot (Dr. C. G.), The Sun. Revised edition, 331
Abel (O.), The Crawling Cracks in the Sandstone of Greifenstein near Kierling in the Wienerwald, 971
Abell (Sir Westcott), History of the Ship, 67
Abetti (G.), Altitude of the Chromosphere in 1928 and Course of the Present Solar Cycle, 862
Adams (Dorothy), The Physiology of Vision, 2 : Dark Adaptation, 599
Adams (L. H.), and R. E. Gibson, The Elastic Properties of Certain Basic Rocks and of their Constituent Minerals, 898
Adams (Prof. R.), and Prof. J. R. Johnson, Elementary Laboratory Experiments in Organic Chemistry, 7
Adamson (Dr. D.), Presidential Address to the Institution of Mechanical Engineers, 661
Adeney (Dr. W. E.), The Principles and Practice of the Dilution Method of Sewage Disposal, 543
Adlam (G. H. J.), A School Certificate Chemistry, 980
Adler (A.), and others, Feelings and Emotions : the Wittenberg Symposium, 8
Ahmad (M.), Persian Alchemy, 462
Aitken (Prof.), Prof. Aitken's Double Stars, 278
Aiyer (K. S. P.), Indian Oligochæta, 424
Albertoni (Prof. P.), Carbohydrate Transformation in the Animal Organism, 739
Alexander (C. P.), The Australian Species of Molophilus (Tipulidae, Diptera), 287
Alexander (N. S.), The *J*-phenomenon in X-rays, 1006
Allan (Dr. H. H.), New Zealand Trees and Shrubs : and how to identify them, 717
Allen (Dr. E. J.), Sir E. Ray Lankester, 313 ; The Origin of Variations, 128
Allen (Dr. E. W.), [death], 994
Allen (Prof. F.), Unitary Behaviour of the Nervous System, 279
Allier (R.), translated by F. Rothwell, The Mind of the Savage, 910
Allmand (Prof. A. J.), and J. W. T. Spinks, Photosensitised Decomposition of Ozone, 651
Allorge (P.), and others, Contribution à l'étude du peuplement des hautes montagnes, 532
Alpatov (W. W.), The Influence of Thyroid Gland Feeding on the Acceleration of the Growth of Larvæ of *Drosophila melanogaster*, 603
Amaldi (E.), The Quantum Theory of the Raman Effect, 359
Ambronn (Dr. R.), Translated by Dr. Margaret C. Cobb. Elements of Geophysics : as applied to Explorations for Minerals, Oil, and Gas, 52
American Geophysical Union, Election of Officers, 243
Ami (Dr. H. M.), Graptolite Centenary, 1829–1929, 766 ; Work of the Canadian School of Prehistory in France in 1929, 1003
Anderson (F. M.), Miocene of Northern Colombia, 71
Anderson (R. J.), Chemical Investigation of Biologically Active Lipoids of Tubercle Bacilli, 675
Andoyer (Prof. H.), [obituary article], 102
Andrade (Prof. E. N. da C.), Molecular Air-Pumps, 657 ; and S. K. Lewer, New Phenomena in a Sounding Dust Tube, 724
Andrews (W. S.), [death], 102
Angeli (A.), The Constitution and Reactions of the Diazohydrates, 638 ; and Z. Jolles, Reduction of Normal Diazo-hydrates, 970
Annenkova (N.), Polychæta from the Relic Lake Palæostom (Western Caucasus) and the Rivers connected with it, 286
Anthony (H. E.), Field Book of North American Mammals, 836
Antoniadi (E. M.), Ancient Greek Astronomy, 106 ; Rotation of Satellites, 595
Appleyard (R.), Claude Chappe, 852
Argentinovskij (J.), A New Cinnabar Ore Deposit in the Urals, 969
Armellini (Prof. G.), Measurements of Double Stars, 862
Trattato di astronomia siderale. Vol. 1, 49
Armitage (Doris Mary), A Challenge to Neurasthenia, 944
Armstrong (A. L.), An Archæological Expedition in Rhodesia, 923
Armstrong (Dr. E. F.), Industrial Catalysis, 47
Armstrong (Prof. H. E.), Prof. C. Moureu, 238 ; Prof. W. H. Perkin, jun., 623 ; The Work of Kekulé, 630
Armstrong-Jones (Sir Robert), Superstition, 769
van Arnam (R. N.), and W. E. Harper, Stellar Spectroscopy, 888
Arneman (W. G.), and J. C. Earl, The Celluloses of some Australian Plants, 359
Arnott (F. L.), elected to an Isaac Newton Studentship of Cambridge University, 743
Arnott (R. F.), E. G. F. Arnott, A. L. Bennett, and Prof. J. Q. Stewart, Kinematographic Record of Sunrise on the Moon, 56
Arnulf (A.), Determination of Angles by the Utilisation of Microscopic Areas, 358
Aron (Prof. M.), Vie et réproduction : notions actuelles sur les problèmes généraux de la biologie animale, 534
Arrow (G. J.), appointed deputy keeper in the department of Entomology of the British Museum, 853
Arup (P. S.), The Composition of Irish Winter Butter, 602
Ashcroft (E. W.), Technical English Vocabulary, 492
Astley (A.), From a Bird-Lover's Diary, 573
Astley (Rev. H. J. D.), Biblical Anthropology compared with and illustrated by the Folk-lore of Europe and the Customs of Primitive Peoples, 223
Asundi (R. K.), and J. W. Ryde, Vibrational Quantum, Analysis of Red Cyanogen Bands, 57
Athanasui (G.), The Influence of Temperature on the Photovoltaic Electromotive Forces, 745
Atkinson (E. C.), Escapement Errors of Pendulum Clock, 933
Atkinson (R. d'E.) Rapid Approximate Calculation, 94
Attems (C.), Dr. L. Berland, and Dr. C. F. C. Beeson, Insects of Samoa, 739
Auger (P.), and D. Skobelzyn, The Nature of the Ultra-penetrating Rays (Cosmic Rays), 252
Ault (Commander J. P.), Chart of the Pacific, 319 ; [death], 883
Austin (Prof. L. S.), [death], 994
Awbery (J. H.), and Dr. E. Griffiths, Apparatus for Determining the Specific Heat of a Material in Powder Form, 1006

Babcock and Wilcox, Ltd., Water-cooled Furnace Walls, 320
Babcock (Prof. E. B.), and Prof. J. L. Collins, Natural Ionising Radiation and Rate of Mutation, 227
Babcock (H. D.), Some New Features of the Atmospheric Oxygen Bands, etc., 467

Badger (Prof. W. L.), and Prof. E. M. Baker, Inorganic Chemical Technology, 537
Bagchee (Dr. K.), A New Species of Cronartium from the Himalayas, 691
Bhattacharjya (D. K.), Second Spark Spectrum of Selium (Se^{++}), 229
Bhattacharya (Prof. D. R.), and Dr. R. S. Das, Golgi Body and Vacuome, 692
Bailey (Dr. Dorothy), and Dr. K. C. Bailey, An Etymological Dictionary of Chemistry and Mineralogy, 789
Bailey (E. B.), appointed professor of geology in Glasgow University, 968
Bailey (R. W.), The Contribution of Manchester Researches to Mechanical Science, 67
Baird (J. C.), and J. H. Prentice, The Changes with Age of the Hydrogen Ion Concentration of Egg White and Egg Yolk, 969
Baird (J. L.), Surmounting a Difficulty in Television, 492
Baker (C.), New Model Microscope, 319
Baker (Prof. H. B.), Effect of Intensive Drying on Chemical Changes, 556
Bakewell (R.), a memorial to, unveiled by Sir Thomas Middleton, 157
Baldet (F.), Periodic Comets, 32
Balfour (Sir Arthur), appointed a member of the Advisory Council to the Committee of the Privy Council for Scientific and Industrial Research, 422
Balfour (Sir Graham), [death], 732
Balfour (H.), South Africa's Contribution to Prehistoric Archæology, 196, 268
Ballantyne (Frances M.), The Development of *Callichthys littoralis*, 825
Bamford (A. J.), Vertical Air-currents as Measured by Pilot Balloons, 77
Bancroft (W. D.): and R. P. Allen, Photochemical Temperature Coefficients, 395; and D. S. Morton, Monatomic Iodine and Molecular Hydrogen, 395
Banks (R. T.), Drilling for Oil with Diamond Drills, 160
Bannister (C. O.), The Crystallisation of Gold from the Liquid State, 430
Bär (Prof. R.), Raman Effect from Powdered Crystals, 692
Barbieri (G. A.), A New Type of Rare Earth Salts, 359; Ferro-cyanomolybdates and Analogous Compounds of Ruthenium and Osmium, 638
Barger (Prof. G.), Preservation of Timber in Sea-Water, 498; The Relation of Organic Chemistry to Biology, 146, 234
Barker (Prof. A. F.), The Shearing of South African Sheep, 816
Barnard (Dr.), South African Branchiopoda, 738
Barnard (J. E.), Ultra-Violet Microscopy, 281
Barnard (K. H.), The Genus *Colophon* (Coleoptera), 78
Barnes (Prof. H. T.), Ice Engineering, 89; Iceberg Detection, 337
Barnes (Dr. R. B.), Fine Structure of Infra-Red Absorption in Organic Compounds and the Raman Effect, 300
Barnes (Dr. W. H.), Crystal Structure of Ice, 857
Barovskij (V.), A New Species of the Genus *Macrolycus* Waterh. (Coleoptera Lycidæ), 358
Barrett (C.), Giant Earthworms of South Gippsland, 387
Barrett (O. W.), The Tropical Crops, 440
Bartlett (F. C.), Experimental Method in Psychology, 149, 341
Bateman (Sir Alfred), [death], 382
Bateson (William), edited, with an Introduction by Beatrice Bateson, Letters from the Steppe: written years 1886–1887, 533; Scientific Papers of, edited by R. C. Punnett. 2 vols., 171
Bather (Dr. F. A.), elected an honorary member of the Museums Association, 68; Modern Sea-Urchins and their Origin, 329
Batson (R. G.), and H. J. Tapsell, Strength of Carbon Steels for Boiler Construction, 161
Battúta, Ibn, Travels in Asia and Africa, 1325–1354, translated and selected by H. A. R. Gibb, 261
Baxandall (F. E.), [obituary article], 732
Baxter (G. P.), and H. W. Starkweather, The Density, Compressibility, and Atomic Weight of Argon (2), 395
Baylis (Dr. H. A.), A Manual of Helminthology: Medical and Veterinary, 261; The "Encyclopædia Britannica", 987
Beach (A. C. G.), Reflection of Polarised Light, 373
Bearden (J. A.), Wave-length of the *K*-lines of Copper using Ruled Gratings, 467
Beattie (Prof. J. M.), Research on Rheumatic Affections, 294
Beauchamp (Earl), installed as Chancellor of London University, 860
Beck, Ltd. (R. and J.), A New Metallurgical Microscope, 551
Becker (E. R.): Methods of Rendering the Rumen and and Recticulum of Ruminants free from their normal Infusorian Fauna, 395; and T. S. Hsiung, The Method by which Ruminants acquire their Fauna of Infusoria, etc., 675
Beckurts (Prof. H.), [death], 589; [obituary], 700
Bedel (C.), The Catalysis of the Solution of Silicon in Hydrofluoric Acid and the influence of Tempering, 862; The Oxidisability of Silicon and its Solubility in Hydrofluoric Acid, 358
Bedos (P.), The Retrogradation of the C_6 Ring into the C_5 Ring with the Aid of the Etherate of Magnesium Bromide, 431
Beebe (Dr. W.), Beneath Tropic Seas: a Record of Diving among the Coral Reefs of Haiti, 476
Beliankin (D.): Chemical Degeneration of Dinas, 969; and M. Bezborodov, Contact-metamorphic Structures in Technical Processes, 781
Bell (V. G.), [death], 520
Belling (Dr. J.), and others, Genetical Studies at Cold Spring Harbor, 461
Bellingham (L.), The Electrification of Omnibuses, 31
Belopolsky (Prof. A.), Apparent Recessional Velocity of Distant Objects, 772
Bemporad (A.), and L. Genovese, The Systematic Errors of the Draper Catalogue, 167
Bennett (A. L.), appointed lecturer in zoology in Edinburgh University, 213
Bennett (M. G.), The Physical Conditions controlling Visibility through the Atmosphere, 861
Benndorf (Prof. H.), The Upper Atmosphere, 108
Bent (A. C.), American Shore Birds, 279
Bent (Mrs. Theodore), [obituary article], 65
van den Berghe (L.), The Sense of Smell and the Mechanism of the Olfactory Currents in some Teleostians, 934
Berliner (Dr. A.), Lehrbuch der Physik in elementarer Darstellung. Vierte Auflage, 542
Berliner (E.), Acoustics of Public Halls, 280; [obituary], 347
Berner (R.), Magnitude of a Force which tends to displace the Continents towards the West, 394
Berry (A.), [death], 455
Berry (A. J.), Volumetric Analysis: with a Chapter on Simple Gravimetric Determinations, Fourth edition, 536
Berry (Prof. E. W.), An Eocene Tropical Forest in the Peruvian Desert, 288; Fossil Plants and Mountain Uplift in the Pacific States, 467; Paleontology, 944
Berry (S. S.), A New Squid, 667
Bert (L.), and M. Anglade, A New Method of Synthesis of Propylbenzene, etc., 862
Berthois (L.), The Heavy Minerals of the Eruptive and Crystallophyllian Rocks of Britanny, 77
Bertrand (G.), and Mme. C. Voronca-Spirt: Titanium in Cryptogams, 285; and Mlle. Voronca-Spirt, Titanium in Animals, 431
Berzelius, the 150th anniversary of the birth of, 661
Besson (M.), Le totémisme, 686
Best (Rev. John H.), From the Seen to the Unseen, 88
Betts (E.), Heraclitus: or the Future of the Films, 649
Bidder (Dr. G. P.), Sir E. Ray Lankester, 346
Bieler (Dr. E. S.), [death], 240; [obituary article], 381
Bierens de Haan (Dr. J. A.), Animal Language in its relation to that of Man, 735; Animal Psychology for Biologists, 790
Bigiavi (D.), Reactions of the Diazohydrates, 674
Bini (G.), Certain Characteristics of the Red Sea with regard to the Nitrogen Cycle, 674
Birge (Prof. R. T.), Further Evidence of the Carbon Isotope, Mass 13, 182; Physical Constants, 461; The Isotopes of Oxygen, 13
Birkhoff (Prof. G. D.), Dynamical Systems, 612
Bishop (Dr. Marian K.), awarded a Grisdale scholarship of Manchester University, 213

Bitter (F.), Magnetic Susceptibility of Nitric Oxide at 296° K. and 216° K., 675
Black (Dr. D.), *Sinanthropus Pekinensis*, 245
Blackett (P. M. S.), P. S. H. Henry, and Dr. E. K. Rideal, A Flow Method for Comparing the Specific Heats of Gases, 825
Blackman (Dr. A. M.), The Papyrus Salt, 206
Blanc (G.), and J. Caminopetros, The Virus of Dengue, 826
Blanchard (E.), and J. Chaussin, The Influence of a Complete Manure on the Osmotic Pressure in some Agricultural Plants, 78
Blaringhem (Prof. L.), Principles et formules de l'hérédité Mendélienne, 407
Blazey (C.), Idiomorphic Crystals of Cuprous Oxide in Copper, 466
Bledisloe (Lord), appointed Governor-General of New Zealand, 887; offer to the nation of a Roman Camp, 817
Bleek (Miss D. F.), Comparative Vocabularies of Bushman Languages, 224
Blegvad (Dr.), Dr. Johansen, and Dr. A. J. C. Jensen, Plaice in Danish Waters, 554
Bles (late Dr. E. J.), Gas Vacuoles of *Arcella*, 245
Blondel (A.), awarded the Kelvin Medal of the Institution of Civil Engineers, 65, 664
Boas (Prof. F.), Anthropology and Modern Life, 754; Materials for the Study of Inheritance in Man, 532
Bodenheimer (Dr. F. S.), and Dr. O. Theodor, The Biblical Manna, 1003
Bodylevskij (V. I.), Fauna of a Bed at Mohn Bay, Spitsbergen, 359
Bogdanov (Prof. E. A.), *Phormia* in *Calliphora* Cultures, 962
Bogitch (B.), The Oxidation and Reduction of the Iron Silicates by Gases, 826
Bolton (E. R.), and K. A. Williams, The Grouping of Fatty Oils with Special Reference to Olive Oil, 780
Bolton (H.), Fossil Insects of the South Wales Coalfield, 861
Bond (Dr. W. N.), Relationship between h, c, and e^2, 408
Bone (Prof. W. A.), Combustion of Acetylene, 839; Effect of Intensive Drying on Chemical Changes, 556
Bonhoeffer (Dr.), Separation of two kinds of Molecules from Hydrogen, 455
Bonnell (B.), An Amphibious Centipede from India, 209
Bonnerjea (Dr. B.), Garo Ethnology, 352
Bonnet (R.), and Tchang-Hyao-Tchi, Overfeeding, 42
Bontflour (R.), Hay Rations for Dairy Cows, 999
Booker (F. W.), New Sub-genera of *Productus* and *Strophalosis* from the Branxton District, 359
Boone (L.), Californian Echinoderms, 496
Borelius (G.), W. H. Keesom, and C. H. Johansson, Kelvin Effect at Low Temperatures, 820
Born (Prof. A.), Über Druckschieferung im varistischen Gebirgskörper, 686
van den Bos (W. H.), The Orbit of γ Centauri, 737
Bose (Sir J. C.), Lecture at the India Office, 103
Bosler (Prof. J.), Faculté des Sciences de Paris: Cours d'astronomie. Tome 3: Astronomique, 49
Bougault (J.), and J. Leboucq, Action of Heat on the Allophanic Amides, 42
Bouhet (C.), The Elliptical Polarisation produced by Reflection at the Surface of Solutions of Fatty Acids in Water, 252
Bouin (Prof. P.), Éléments d'histologie. Tome 1, 88
Bourguel: A relation between the Boiling Point and the Molecular Structure of Cis-trans Ethylenic Saturated and Acetylenic Acids, 77; and Mlle. V. Gredy, The Selective Action of a Hydrogen Catalyst, 934
Boving (J. O.), Hydraulic Pneumatic Engineering, 1001
Bowden (Dr. F. P.), elected a fellow of Gonville and Caius College, 931
Bowen (E. J.), and E. L. Tietz, The Oxidation of Acetaldehyde by Oxygen, 914
Bowen (N. L.), The Evolution of the Igneous Rocks, 474
Bowen (Prof. R. H.), [death], 520
Bowen and Schairer, The System: Leucite-Diopside, 774
Bower (W. R.), [obituary article], 955
Bowman (Dr. A.), Line Fishing in the Moray Firth, 387
Boys (Prof. C. V.), gift of a sundial to the Royal Botanic Gardens, Kew, 965; Progressive Lighting, 54
Braarud (T.), B. Föyn, and H. H. Gran, Biology of Norwegian Lakes, 73
Bradford (F. C.), and B. G. Sitton, Defective Graft Unions in Apple and Pear, 555
Bradford (Dr. S. C.), A Bibliography of Applied Science, 942; The Subject Index to Periodicals, 122
Bradley, Jr. (Prof. J. H.), The Earth and its History: a Textbook of Geology, 836
Bragg (Lady), [death], 589
Bragg (Sir William), appointed a member of the Advisory Council to the Committee of the Privy Council for Scientific and Industrial Research, 422
Bragg (Prof. W. L.), Diffraction of X-rays by Two-Dimensional Crystal Lattice, 125
Brain (W. R.), and E. B. Strauss, Recent Advances in Neurology, 755
Branfoot (M. H.), (M. H. Carré), The Pectic Substances of Plants, 709
de Brath (S.), The Scientific Examination of Facts, 734
Bridel (M.), and J. Rabaté, Variations in the Composition of New Branches of *Amelanchier vulgaris*, 934
Bridgman (P. W.), and J. B. Conant, Irreversible Transformations of Organic Compounds under High Pressures, 675
Briggs (Prof. H.), Mining Subsidence, 537; The Ventilation of Mines: Generation of the Air Current, 537
Briner (E.): P. Schnorf, and R. Meyer, The Ozonation of the Gaseous Unsaturated Hydrocarbons, 43; and R. Wunenburger, The Ozonation of Acetylene, 215
Brinkworth (J. H.), On the Temperature Variation of the Specific Heats of Hydrogen and Nitrogen, 825
British Drug Houses, Ltd., Simple Soil-Testing Outfit, 425
Broch (Dr. H.), Northern Hydrozoa, 387
Brocq-Rousseu, Mme. Z. Gruzewska, and G. Roussel, The influence of the Ionic Concentration of the Medium on the Activity of the Amylase of Horse Serum, 826
de Broglie (L.), awarded the Nobel Prize for physics for 1929, 883
Bromehead (C. N.), Occurrence of Sea-urchins on the Foreshore in Britain, 373
Bromwich (Dr. T. J. I'A.), [death], 347; [obituary article], 520
Brooks (A.), The Food of Birds, 666
Brooks (Dr. C. E. P.), Climate: a Handbook for Business Men, Students, and Travellers, 982
Brooks (E. F.), Observing Sea Temperature, 962
Brooks (F. T.), Plant Diseases, 257
Broom (Dr. R.), Australoid Element in the Korannas, 507
Brown (Major H. C.), and Dr. J. C. Broom, Electric Charge in its relation to Complement Fixation, 794
Brown (Ida A.), Monzonitic and Nepheline-bearing Rocks of Mount Dromedary, N.S.W., 287; A Garnet-bearing Dyke near Moruya, N.S.W., 395
Brown (J. H.), Bourne or Gypsey Flows, 159
Browne (Sir James Crichton), the eighty-ninth birthday of, 849
Browne (W. R.), An Outline of the History of Igneous Action in N.S.W. until the close of the Palæozoic Era, 286
Bruce (A. B.), [death], 65
Brukl (A.), The Quantitative Analysis of Gallium (3), 745
Brüninghaus (L.), The Existence of a Conducting State of so-called Insulating Liquids, 41
Brunner (C. T.), The Problem of Motor Transport: an Economic Analysis, 124
Brunschwig (R.), and L. Jacqué, A Method of Testing Motor Benzene, 780
Brunton (G.), The Origin and Affinities of the Badarian Culture, 206
Brush (Dr. C. F.), [death], 102
Bryan (W. H.), Fossil Laterite from Southern Queensland, 512
Bryce (D. L.), Encystment in Rotifers, 889
Buchner (Prof. E. F.), [death], 520
Budgen (N. F.), Pinholes in Cast Alluminium Alloys, 466
de Buen (D. R.), "El Tunel del Estrecho de Gibraltar", 771
Bull (H. I.), and Prof. W. E. Garner, Heat of Absorption of Oxygen and Nitric Oxide on Charcoal, 409
Bullard (E. C.), and R. M. Margoei, awarded the Denman Baynes studentship of Cambridge University, 164
Buller (Prof. A. H. R.), presented with the Flavelle Medal of the Royal Society of Canada, 110

Bulloch (Prof. W.), Dr. L. H. Lampitt, and J. H. Bushill, Catgut and its Sterilisation, 855
Burger (G.), The Separation of Alkalis in Minerals with the Interferometer, 827
Burgess (A. H.), Experimental Hop Drying, 34
Burgess (Prof. A. H.), Influence of other Sciences upon the Practice of Modern Surgery, 154
Burgess (M. J.), and Prof. R. V. Wheeler, Ignition of Firedamp, 598
Burgess (W. L.), J. Craigie, and W. J. Tulloch, A Flocculation for Disease, 703
Burkitt (M. C.), Rock Carvings in the Italian Alps, 33
Burney (Comdr. Sir Charles Dennistoun), The World, the Air, and the Future, 939
Burnham (T. H.), Engineering Economics, 538
Burns (Prof. D.), An Introduction to Biophysics. Second edition, 722
Burnside (the late Dr. W.), Theory of Probability, 297
Burton (H. E.), The Satellites of Mars, 665
Burton (M.), Deep-water Sponges, 279
Busbridge (Miss I. W.), awarded the Sir John William Lubbock memorial scholarship prize of London University, 778
Bush (Prof. V.), with an appendix by Prof. N. Wiener, Operational Circuit Analysis, 538
Busk (H. G.), Earth Flexures; their Geometry and their Representation and Analysis in Geological Section, with special reference to the problem of Oil Finding, 644
Butler (B. S.), and W. S. Burbank, Copper Deposits of Michigan, 633
Butler (C. P.), appointed first senior observer at the Solar Physics Observatory, Cambridge, 968
Butt-Thompson (Capt. F. W.), West African Secret Societies: their Organisations, Officials, and Teaching, 872
Buxton (Dr. P. A.), Researches in Polynesia and Melanesia: an Account of Investigations in Samoa, Tonga, the Ellice Group, and the Hebrides in 1924, 1925. Parts 5-7, relating to Human Diseases and Welfare, 910
Buxton and Darbishire, Petal-colour and Hydrogen Ion Concentration, 319
Byrd (Commander R. E.), Antarctic Flight, 884

Cabrera (B.), and A. Duperier, The Paramagnetic Properties of the Rare Earths, 215
Cade (S.), Radium Treatment of Cancer, 836
Caglioti (V.): Polyhalides (1), 79; and L. Malossi, Double sulphates of Bismuth and Alkali Metals (2), 862
Cajori (Prof. F.), A History of Mathematical Notations. Vol. 1: Notations in Elementary Mathematics, 4; The Translator of Newton's "System of the World," 513
Caley (E. R.), A Qualitative Reagent for Sodium, 389
Callaghan (A. R.), The Development of the Inflorescence of *Avena sativa* L., 467
Callendar (Prof. H. L.), New Steam Tables, 35
Calvet (J.), Influence of Various Salts on the Solution of Pure Aluminium in Hydrochloric Acid, 358; The Attack of Aluminium by Ammoniacal Solutions, 780; The Heat of Hydrolysis of the Amides: Acetamide, 781
Cambi (L.), and A. Clerici, Reactions between Ferrous Compounds and Nitric Oxide, 79
Cambridge Instrument Co., Ltd., The Katharometer in Gas Analysis, 740
Cameron (Dr. T. W. M.), appointed lecturer in helminthology in Edinburgh University, 213
Campbell (Dr. A. N.), The Physical Identity of Enantiomers, 792
Campbell (Dr. N. R.), The Grant of Invalid Patents, 875
Canaud (A.), The Electrolysis of Water with Alternating Current, 41
Cantacuzène (Prof.), Tests with 'Bile-Calmette-Guérin', 768
Canziani (Estella), Through the Apennines and the Lands of the Abruzzi: Landscape and Peasant Life, 52
Capitan (Prof. L.), [obituary article], 660
Carbone (Dr. D.), Vaccination of Silkworms, 33
Cardwell (A. B.), Effects of a Crystallographic Transformation on the Photoelectric and Thermionic Emission from Cobalt, 603
Carlgren (Dr. O.), and Dr. T. A. Stephenson, Antarctic Anemones, 928
de Carli (F.), Viscosity Isotherms of Binary Mixtures (3), 970
Carpenter (E. F.), Reported New Comet, 998
Carpenter (Dr. G. D. Hale), Mimicry, 183
Carriére (Z.), Sound Vibrations, 498
Carter (H. J.): Australian Coleoptera. Notes and New Species (6), 324; and E. H. Zeck, Australian Coleoptéra of the family Dryopidæ, 928
Cassinis (U.), and L. Bracaloni, Normal Alcoholemia during Physical Exercise, 168
Castellani (Sir Aldo), The Influence of Climate upon the Health of Europeans in the Tropics, 629
Caton-Thompson (Miss G.), The Southern Rhodesian Ruins, 619; The Zimbabwe Ruins, 275, 390
Caum (E. L.), Hawaiian Non-Marine Mollusca, 70
Cavasino (Prof. A.), Italian Earthquake of Mar. 27, 1928, 706
Cawston (Dr.), Resistance of Limnæidæ and their Allies to Dessication, 353
Cawston (F. C.), The Problem of the Ventilation of Iron Roofs in the Tropics, 897

TITLE INDEX

Abbey-Cwmhir, Radnorshire, The Geology of the District around, R. O. Roberts, 166

Aberdeen University, award of doctorates, 164; bequest to Marischal College by Dr. H. Cook, 673

Abra (=*Syndosmya*) *alba*, *Donax vittatus*, Severe Environmental Mortality among, and other Organisms off the Lancashire Coast, Prof. J. H. Orton, 911

Abraxas grossulariata, Spermatogenesis of, Effect of X-radiation on the, Prof. J. B. Gatenby, R. N. Mukerji, and Sylvia Wigoder, 780

'Absolute', The, and 'Relative', W. W. L., 126

Acclimatisation, Prof. R. de C. Ward, 770

Acetaldehyde, The Oxidation of, by Oxygen, E. J. Bowen and E. L. Tietz, 914

Acetate, Basic, and Basic Sulphate of Gallium and Gallium Oxalate, A. Tchakirian, 431

Acetone in the Gaseous State, The Thermal Decomposition of, F. O. Rice and R. E. Vollrath, 898

Acetylene: Combustion of, Prof. W. A. Bone, 839; The Homogeneous Oxidation of, G. B. Kistiakowsky and Dr. S. Lenher, 761; The Ozonation of, E. Briner and R. Wunenburger, 215

Acid Plagioclases, On the Composition-plane of [010]-twins in the, F. C. Phillips, 896

Acoustics of Public Halls, E. Berliner, 280

Adaptation: Prof. A. Meek, 509; Prof. D. M. S. Watson, 195, 231; J. T. Cunningham, 617

Adaptations and the Influence of Light on Animal Tissues, M. Perkins, 759

Adiabatic Microcalorimeter, The Application of the, to Measurements of Quantities of Heat emitted, Mlle. A. Dorabialska, 969

α-diacetylene Hydrocarbons, The Additive Properties of the, V. Grignard and Tchéoufaki, 114

α-diketones, The Tautomerism of the, H. Moureu, 42, 114

Adipose Cells, The Structure of, G. Levi and G. C. Dogliotti, 638

Admiralty, Scientific Research and Experiments Department of the, Dr. C. V. Drysdale appointed director of the, 629

Adrenal Cortex, A Function of the, Prof. Swale Vincent and J. H. Thompson, 445

Aeronautical Research in Great Britain, 560

Aeroplanes, Giant, and their Design, Dornier, 100

Afforestation of Peat Lands in Sweden, C. Malmström, 111

Afghanistan, Agricultural, Prof. N. I. Vavilov and D. D. Bukinich, 74

Africa: and Science, J. H. Hofmeyr, 135; Marriage in, E. Torday, 496; Native Education in, 829; Social Organisation in, Dr. Thurnwald, 999

African: Cave Fish with very Small Eyes, An, J. Pellegrin, 358; Game Tracks: In, Wanderings with a Rifle through Eastern Africa, F. L. Puxley, 980

Agricultural: Afghanistan, Prof. N. I. Vavilov and D. D. Bukinich, 74; Botany, National Institute of, Annual general meeting of the, 207; Economics, Prof. G. O'Brien, 531; Entomology, D. H. Robinson and S. G. Jary, 534; Resources of the Empire, The development of the, Sir Robert Greig, 198

Agriculture: and Industry in the Colonies or Territories, Proposed Government help for, J. H. Thomas, 103; and the Empire, Sir Robert B. Greig, 304; The Future of, 81

Agropyrons, Chromosome Numbers in the, F. H. Peto, 181

Ägyptischer Wüsten- und Salzpflanzen: Der Wasserhaushalt vom Standpunkt einer experimentellen und vergleichenden Pflanzengeographie aus, Dr. O. Stocker, 293

Air-currents, Vertical, as Measured by Pilot Balloons, A. J. Bamford, 77

Air Ministry: Meteorological Office. Réseau Mondial 1922: Monthly and Annual Summaries of Pressure, Temperature and Precipitation based on a World-wide Network of Observing Stations, 541

Air Photographs, Survey by, Capt. M. Hotine, 929

Air-Pumps, Molecular, Prof. E. N. da C. Andrade, 657

Airships: and Arctic Meteorology, 785; The Magnetic Guidance of Safety Aerodromes, W. Loth, 826

Air Surveys, Value and Importance of, Sir Charles Close, 31

Alaska, Aerial Survey in, R. H. Sargent and F. H. Moffit, 597

Alcoholemia, Normal, during Physical Exercise, U. Cassinis and L. Bracaloni, 168

Alcoholic: Fermentation, The Supposed Rôle of the Glyceric Aldehyde and Glyceric Acid in, S. Kostytchev and C. Egorova, 286; Hydrochloric Acid, Action of, on certain Unsaturated Ketones, B. Coffey and Prof. H. Ryan, 251

Alcoholism, Dr. J. D. Rolleston, 245

Aldehydes, The Condensation of, with Benzylacetoacetic ester, Prof. H. Ryan, W. B. Cornelia, and P. Hurley, 251

Alexander's Track to the Indus, On, Sir Aurel Stein, 531

Alfalfa, J. F. Cox and C. R. Magee, 369

Algæ, Respiration of the, Action of High Pressures on the, M. Fontaine, 862

Algol, Interpretation of the Behaviour of, and the Variability of the Velocity of Light, M. La Rosa, 167

Alkaline: Carbonates, The Action of the, on Lead Bromide, Iodide and Nitrate in Aqueous Solution, Mme. N. Demassieux, 745; Oxalates, The Action of, on the Halogen Salts of Lead in Aqueous Solution, Mme. N. Demassieux, 781

Alkalis in Minerals, Separation of, with the Interferometer, G. Burger, 827

Alkyl Sulphites, The Conversion of, into Chlorsulphonic Esters and into the Neutral Sulphates, R. Levaillant, 745

Allantoin in the Presence of Urea, The Quantitative Biochemical Analysis of, R. Fosse, A. Brunel, and P. de Graeve, 42

Allbutt, Sir Thomas Clifford, K.C.B., The Right Hon. A Memoir by Sir Humphry Davy Rolleston, Bart., 833

Allophanic Amides, Action of Heat on the, J. Bougault and J. Leboucq, 42

$Al(NO_3)_3 - Fe(NO_3)_3 - H_2O$ and $KNO_3 - Fe(NO_3)_3 - H_2O$ at 0° and 40°, The Systems, G. Malquori, 79

Alpha-particles from Radium, Rate of Emission of, F. A. B. Ward, C. E. Wynn-Williams, and H. M. Cave, 932

α-rays, Magnetic Spectrum of the, The Fine Structure of the, S. Rosenblum, 114

Alphabets, The Origin of, Sir R. A. S. Paget, Bart., 228

Alto da Serra, São Paulo, Brazil, The Biological Station of, Mrs. E. S. Grubb, 1006

Aluminium: Alloys: Cast, Pinholes in, N. F. Budgen, 466; The Corrosion of, in Superheated Steam, L. Guillet and Ballay, 826; and its Alloys, A. G. C. Gwyer, 430; in Hydrochloric Acid, Influence of various Salts on the Solution of Pure, J. Calvet, 358; The Attack of, by Ammoniacal Solutions, J. Calvet, 780

Amelanchier vulgaris, Variations in the Composition of New Branches of, M. Bridel and J. Rabaté, 934

American: Geophysical Union, election of officers, 243; Indian as Inventor, The, Baron Erland Nordenskiöld, 850; National Research Council's Information Service, Pamphlets of the, 322; Shore Birds, A. C. Bent, 279

Amides: The Heat of Hydrolysis of the Acetamide, E. Calvet, 781

Amino Acids, The Biochemistry of the, Prof. H. H. Mitchell and T. S. Hamilton, 944

1-amino-2-phenylazonaphthalene-4-sulphonic acid, Condensation of, G. Charrier, 970

Ammonia: Absorption and Excretion of, by the Roots of Plants, D. N. Prionishnikov and V. N. Ivanova, 394; Action of, on Phosphorus Pentoxide, Harris and Wooster, 320

Ammonium Permanganate, Direct Electrolytic Preparation of, G. Rapin, 114

Amphibious Centipede from India, An, B. Bonnell, 209
Andaman Islands, The Forests of the, A. Rodger, 249
Aneroid Barometer and Plane Table in Geological Mapping, The Use of the, H. G. Raggatt and F. W. Booker, 359
Angles, A Method for the Determination of, by the Utilisation of Microscopic Areas, A. Arnulf, 358
Animal: Evolution, A Novel Theory of, A. H. Clark, 159; Habits and their Association with Disease, H. Fox, 424; Language in its Relation to that of Man, Dr. J. A. Bierens de Haan, 735; Nutrition, Minerals and, Prof. T. B. Wood, 437; Organisms, Action of X-rays on, N. N. Netchayeva, 286; Psychology for Biologists, Dr. J. A. Bierens de Haan, 790; Remains, Preservation of, Dr. J. Parkinson, 56
Antarctic: Anemones, Dr. O. Carlgren and Dr. T. A. Stephenson, 928; Flight in the, Commdr. R. E. Byrd, 884; Further Flights in the, Sir Hubert Wilkins, 553; Meteorology, 967
Ante-natal Clinics: their Conduct and Scope, 385
Anthrax, Vaccination against, Dr. M. Mazzucchi, 889
Anthropology: and Blood-groups, Dr. H. Woollard and Dr. J. B. Cleland, 889; and Modern Life, Prof. F. Boas, 754; Philosophy of, 754; The Value of, Lord Passfield, 884
Antipoliomyelitic Serum, Determination of the Activity of, Prof. S. Flexner and C. P. Rhoads, 603
Antiquity, December, 997
Antistreptococcic Serum, The Therapeutic Results given by a New, H. Vincent, 41
Antituberculous Chemotherapy (Copper and the Rare Earths), Researches on, T. Stephani and E. Cherbuliez, 215
Ants, Bees and Wasps, Sir John Lubbock (Lord Avebury). New edition, edited and annotated by Dr. J. G. Myers, 534
Anura, Crystalline in the Larvæ of, Regeneration of the, P. Pasquini and A. della Monica, 970
Apatite Deposits in the Khibin Tundras, V. I. Vlodavec, 167
Apatites, Changes in the Coloration of, submitted to Heating, A. Tsvetkov, 969
Ape-breeding Farm, An, 886
Apennines and the Lands of the Abruzzi: Through the, Landscape and Peasant Life, Estella Canziani, 52
Apple and Pear, Defective Graft Unions in, F. C. Bradford and B. G. Sitton, 555
Aquaria for Rearing Minute Organisms requiring Running Water, C. Dover, 336
Aquarium Keeping, Dr. W. Klingelhöffer, 819
Arabia, Unknown Tribes in, B. Thomas, 705
Arcella, Gas Vacuoles of, late Dr. E. J. Bles, 245
Archæological: Research, Need of International Effort in, Sir Rennell Rodd, 769; Survey by Air, Col. and Mrs. Lindbergh's, 995
Arcs, The Positive Column in, Dr. Langmuir and L. Tonks, 740
Arctic: Bird Fauna of the, Origin of the, Prof. A. Tougarinov, 777; Meteorology, Airships and, 785
Arcturus, Radial Velocity of Suspected Variation in the, W. Schaub, 595
Argon: in the Solar Corona, Prof. H. N. Russell and Dr. I. S. Bowen, 351; The Density, Compressibility, and Atomic Weight of (2), G. P. Baxter and H. W. Starkweather, 395; Trebly Ionised, Spectrum of, D. S. Jog, 303
Arithmetik in strenger Begründung, Die, Prof. O. Hölder. Zweite Auflage, 943
Arkansas, Lower Carboniferous Fossils in, G. H. Girty, 739
Armourers and Brasiers' Company's research fellowships in metallurgy, Dr. W. Hume Rothery elected to the, 105
Arsenic, Doubly Ionised, Spectrum of, A. S. Rao and Dr. A. L. Narayan, 229
Artificial Silk, Prof. F. Reinthaler. Enlarged and revised edition translated by Prof. F. M. Rowe, 476
Arundel, A Description of the High Stream of, the Heads and Risings thereof; the Sundry Kinds of Fishes therein in their several Haunts; the Fishermen, and their Care and Service in preserving the Fish in Roading Time; the Swans and Eyries, and other Fowl in their several Limits; the Water Bailiff of the aforesaid High Stream in Arundel Rape, his Fees, Dues, and Duties. Edited, with Introduction, Notes, Map, and Index, by J. Fowler, 172
Ashes of the Blood and of Organs, The Spectrographic Analysis of the, P. Dutoit and C. Zbinden, 166
Asia and Africa, Travels in, 1325–1354, Ibn Battúta. Translated and selected by H. A. R. Gibb, 261
ASLIB. Information, 553
Aspergillosis, Dr. V. Pettinari, 460
Asphalt: Detrital, J. Gilluly, 740; Emulsions, K. A. Clark, 774
Asphalts, J. S. Miller, 354
Astronomia siderale, Trattato di, Prof. G. Armellini. Vol. 1, 49

ASTRONOMICAL NOTES.

Comets:
Periodic Comets, F. Baldet, 32; Two New Comets, 317; Orbits of Neujmin's and Forbes's Comets, *b* 1929 and *c* 1929, 351; Comets Neujmin and Forbes, 495; Comet Schwassmann-Wachmann, 631; Reported New Comet, E. F. Carpenter, 998
Instruments:
Silvering the 100-inch Mirror at Mount Wilson, R. W. Porter, 423; Three Huyghens Lenses, Profs. R. A. Sampson and A. E. Conrady, 595; The New Telescope for Edinburgh Observatory, 665; Spectrohelioscope at Greenwich, 888
Meteors:
July and August Meteors, W. F. Denning, 106; Large Meteors, J. Stokley, 158; Period of the Lyrid Meteors, Maltzev, 158; Brilliant Detonating Fireball on July 28, 244; Telescopic Bielid Meteors, Prof. C. P. Olivier, 278; The August Perseids of 1929, W. F. Denning, 317; A Flashing Meteor, W. F. Denning, 423; Recent Fireballs, W. F. Denning, 926
Observatories:
Lembang Observatory, Java, 386; Bergedorf Observatory, 459; Greenwich Observations, 1927, 704
Planets:
Origin of the Planetary System, Dr. H. Jeffreys, 32; New Minor Planet, 69; Measures of the Brightness of Earth-shine, Prof. H. N. Russell, 106; The Observatories of Paris and Meudon, 244; Report of the Cape Observatory for 1928, 244; Future of the Moon, Dr. H. Jeffreys, 317; The Puzzle of the Major Planets, Prof. H. N. Russell, 351; General Perturbations of Minor Planets by Jupiter, 495; The Satellites of Mars, H. E. Burton, 665; Mars, A. Nodon, 704; Occultation of Jupiter by the Moon on Oct. 28, 1928, 704; Interesting New Minor Planet, 737; Changes on Jupiter, 854; Jupiter, Rev. T. E. R. Phillips, 888; Commensurabilities of Periods of Planets and Satellites, L. W. Topham, 926
Stars:
Catalogue of the Comparison Stars for Eros, 69; The Nebula in Andromeda, Dr. E. Hubble, 244; Prof. Aitken's Double Stars, Prof. Aitken, 278; Starlight, Prof. H. N. Russell, 386; Variation of the Calcium *K* Line with Distance in Early Type Stars, Dr. J. H. Oort, 386; The Discovery of Proxima Centauri at Johannesburg, 495; Suspected Variation in the Radial Velocity of Arcturus, W. Schaub, 595; The Orbit of Centauri, W. H. van den Bos, 737; Apparent Recessional Velocity of Distant Objects, Prof. A. Belopolsky, 772; A Catalogue of Dynamic Stellar Parallaxes, Prof. H. N. Russell and Charlotte E. Moore, 772; The Binary Star 70 Ophiuchi, R. Tschilschke, 854; The Star-cloud in Scutum, C. J. Krieger, 854; Stellar Spectroscopy at Dominion Observatory, Victoria, R. N. van Arnam; W. E. Harper, 888; Motions of the Planetary Nebulae, Prof. C. D. Perrine, 998
Sun:
Solar Activity, 69; Curve of Solar Activity from 1877 to 1928, L. Taffara, 278; Argon in the Solar Corona, Prof. H. N. Russell and Dr. I. S. Bowen, 351; Attempts to Photograph the Corona without an Eclipse, A. Hnatek, 459; Recent Sunspots, 631; Recent Solar Activity, 737; Solar Activity, 888; Naked-eye Sunspot, 998

Miscellaneous :
Russian Society for the Study of the Universe, 69 ; Ancient Greek Astronomy, E. M. Antoniadi, 106 ; Curvature of Space, Dr. E. P. Hubble, 158 ; Stark Effect in Stellar Spectra, Dr. O. Struve, 278 ; The Cowell Method of Computing Perturbations, Dr. G. Stracke, 423 ; Rotation of Satellites, E. M. Antoniadi, 595 ; Aurora, W. B. Housman, 926

Astronomy : Ancient Greek, E. M. Antoniadi, 106 ; A Source Book in, Prof. H. Shapley and Helen E. Howarth, 218 ; Treatises on, 49
Athens, British School at, Annual of the, No. 28, Session 1926–1927, 88
'Anthropoid' in South America, The, of Dr. de Loys, Dr. Montandon, 420
Atlantic Earthquake of Nov. 18, 1929, The, Dr. C. Davison, 859
Atmospheric : Electricity, 388 ; Pressure, Effect of, on the Frequency of a Tuning-fork, Y. Namba, 511 ; Oxygen Bands, etc., Some New Features of the, H. D. Babcock, 467 ; Ozone, Drs. Götz and Dobson, 556
Atomic : Frequencies in Solids, Calculation of the, R. de Mallemann, 933 ; Hydrogen, Reactions of, Urey and Lavin, 963 ; Kernels, Repulsion of, W. M. Latimer, 962
Atoms, A Magnitude permitting a New Classification of, G. Fournier, 114
Auckland Institute and Museum, Annual Report of the, 384
Audio-frequency Oscillator, A Simple, C. W. Oatley, 246
Aurora Rays, Sunlit, The Spectrum of, as compared with the Spectrum of Lower Aurora in the Earth's Shadow, Prof. C. Størmer, 263
Auroræ, W. B. Housman, 926
Auroral Spectrum : The, V. M. Slipher and L. A. Sommer, 668 ; Variations of Intensity Distribution of the, and the possible Influence of Sunlight, Prof. L. Vegard, 947
Austenite into Martensite, A Transformation of, D. Lewis, 72
Australasian Association, Report of the Nineteenth Meeting of the, 458
Australia : Appointments to the Colonial Service, Appointment of a committee of advice on, 214 ; and New Zealand : A Tour in, Grass Land and other Studies, Prof. R. G. Stapledon, 530 ; Establishment of a Division of Soils Research, 206 ; Gift for an Animal Health Laboratory in, F. D. McMaster, 457 ; State-aided Publication of Scientific Memoirs, 628
Australian : Asilidæ, A New Classification of the (4), G. H. Hardy, 467 ; Bombyliidæ of the Subfamilies Exoprosopinæ, etc., in the German Entomological Museum, Berlin, F. H. S. Roberts, 971 ; Coleoptera. Notes and New Species (6), H. J. Carter, 324 ; of the Family Dryopidæ, H. J. Carter and E. H. Zeck, 928 ; Part 6, A. H. Elston, 897 ; Diptera, Notes on (20), J. R. Malloch, 466, (2) 781, (22) 971 ; Flies of the Genus *Cerdistus* (Asilidæ), Identity of, described, G. H. Hardy, 324 ; Œnochromidæ (Lepidoptera), Revision of, A. J. Turner (1), 971 ; Physicists, Second Meeting of, 997 ; Physiologic Forms of *Puccinia graminis tritici*, The Origin of Two New, W. L. Waterhouse, 324 ; Plants, The Celluloses of some, W. G. Arneman and J. C. Earl, 359 ; Seagrasses, List of, C. H. Ostenfeld, 43
Australoid Element in the Korannas, Dr. R. Broom, 507
Automaton : or the Future of the Mechanical Man, H. S. Hatfield, 440
Autoxidation, Existence of a Chemical Equilibrium in, A. Gillet and D. Guirchfeld, 896
Avena sativa L., Development of the Inflorescence of, A. R. Callaghan, 467
Aviation and the Future, Dr. G. Merton, 939
Avonian Succession in the South of the Isle of Man, The, H. P. Lewis, 1006
Azande Oracles, E. E. Evans-Pritchard, 738

Bacillus coli, The Pathogenic Effects Exercised on Man and Animals by the Neurotrope Exotoxin of, H. Vincent, 503
Backward Peoples, The Economic Position of, 469
Bacterium malvacearum E. F. S., The Morphology and Cytology of, R. H. Stoughton, 780
Badarian Culture, G. Brunton, 206
Bahamas, a Severe Hurricane in the, 550
Balkan Peninsula : The Plant-Life of the, a Phyto-geographical Study, Dr. W. B. Turrill, 6
Ball, Rouse, Lecture, Prof. S. Chapman, 19
Balloons for Upper Air Work, G. Chatterjee, 793
Bartol Research Foundation, Work at the, 1928–29, 458
Base Exchange and its Bearing on the Formation of Coal and Petroleum, E. Mackenzie Taylor, 113
Basic Rocks, The Elastic Properties of Certain, and of their Constituent Minerals, L. H. Adams and R. E. Gibson, 898
'Basket-Maker' Site in New Mexico, A, F. H. H. Roberts, 773
Basutoland, A Natural History Excursion into, Dr. H. Scott, 825
Bateson : and Mendelism, Prof. T. H. Morgan, 171 ; William, Scientific Papers of, edited by R. C. Punnett. 2 Vols., 171
Batteries with a Fused Electrolyte, G. I. Costeanu, 252
Batu Caves, Fauna of the, C. and Mrs. Dover, 1004
Beakers from the Isle of Skye, W. L. Scott, 666
Bearings and Lubrication, F. Hodgkinson, 891
Beavers of the Palearctic Region, The, M. K. Serebrennikov, 394
Beck Hadfield Metallurgical Microscope, The, 551
Bee, The Visual Acuity of the, and its Relation to Illumination, S. Hecht and E. Wolf, 215
Beef : Home-Killed, 823 ; The Conditioning or Ripening of, T. Moran and E. C. Smith, 822
Behaviour, Anatomy and the Problem of, Dr. G. E. Coghill, 648
Beit : Fellowships for Scientific Research, elections to, 112 ; Memorial Fellowships for Medical Research, elections to, 156 ; Alfred, Bridge, The, across the Limpopo River, 421
Belfast Naturalists' Field Club, Miss W. J. Sayers elected president of the, 350
Benzene, The Electrolytic Chlorination of, in Methyl Alcohol Solution, P. Jayles, 896
Benzol, Fluorescence of, Raman Spectrum and, C. V. Shapiro, 372
Benzole Research Committee of the National Benzole Association and the University of Leeds, Sixth Report of the Joint, 635
Bergedorf Observatory, Annual Report for 1928, 459
Bergiola Stschelk (Orthoptera, Tettigonioidea), The Genus, E. Miram, 394
Beta-particles, the Passage of Fast, through Gases, Dr. E. J. Williams and F. R. Terroux, 932
Biblical Anthropology Compared with and Illustrated by the Folklore of Europe and the Customs of Primitive Peoples, Rev. H. J. D. Astley, 223
Bibliographie, Institut International de, Annual Conference of the, 559
Bibliography of Applied Science, A, Dr. S. C. Bradford, 942
'Bile-Calmette-Guérin', Tests with, Prof. Cantacuzène ; Prof. Woodruff and Mr. Gregory, 768
Binary Mixtures, Viscosity Isotherms of, F. de Carli (3), 970
Biological : Principles : a Critical Study, J. H. Woodger, 909 ; Research, Statistics and : Dr. R. A. Fisher, 266 ; Dr. E. S. Pearson, 615
Biologie : Theoretische, J. von Uexküll, Zweite Auflage, 83 ; wissenschaftliche : Jahresbericht über die, Herausgegeben von Prof. T. Péterfi. Band 1, 262 ; Methodik der, Herausgegeben von Prof. T. Péterfi. Band 1 : Allgemeine Morphologie. Band 2 : Allgemeine Physiologie, 223
Biology : A Philosophy of, Prof. E. W. MacBride, 83 ; in the Universities, Study of, 601 ; of Lakes in Kenya, Penelope M. Jenkin, 574 ; of Norwegian Lakes, Braarud, B. Föyn, and H. H. Gran, 73 ; Philosophy in, F. S. Marvin, 259
Biophysics, An Introduction to, Prof. D. Burns. Second edition, 722
Biota, West Indian, in New Caledonia, Prof. T. D. A. Cockerell, 615

Bird : Behaviour, An Introduction to the Study of, H. Eliot Howard, 523 ; Courtship, 523 ; Fauna of the Arctic, Origin of the, Prof. R. Tougarinov, 777 ; Life, Influence of Roadways on, Miss Jean M. Linsdale, 552 ; Lover's Diary, From a, A. Astley, 573 ; Malaria, Relapse in, R. D. Manwell, 388 ; Sanctuaries, Annual Report for 1928 of, 551
Birds : Sexual Behaviour in, Dr. F. H. A. Marshall, 655 ; E. Selous, 761 ; The Food of, A. Brooks, 666 ; Way-finding of, G. J. van Oordt and C. J. A. C. Bol, 107
Birmingham University : Conferment of degrees, 39, 968 ; Mining Research Laboratory, Report for 1928, 594 ; The Mining Machinery Laboratory, 824
Bishop, Bernice P., Museum, *Bulletins* of the, 703
Bismuth and Alkali Metals, Double Sulphates of, V. Caglioti and L. Malossi (2), 862
Bismutotantalite, a New Mineral from Uganda, E. J. Wayland and Dr. L. J. Spencer, 76
Blast Furnace Practice, F. Clements, Vol. 1, 401
Blepsiinæ, The Subfamily (Pisces, Cottidæ) in the Pacific, P. Schmidt, 897
Block Models, Patterns for the Construction of, Dr. F. Smithson, 664
Blood : a Study in General Physiology, Prof. L. J. Henderson, 542
Bodfean, South-western Carnarvonshire, The Geology of the Country Around, C. A. Motley and A. Heard, 166
Bombay Deccan, Irrigation Schemes in the, E. C. Snelgrove, 67
Bopyridæ, Mode of Feeding of the, B. W. Tucker, 985
Borax Solubility Test, A New, for Lactic Acid or Natural Sour Casein, W. R. Mummery and F. Bishop, 780
Boron, Organo-aromatic Derivatives of, E. Pace, 970
Borrowdale Volcanic Series of the Kentmere Area, Westmoreland, the Petrography of the, G. H. Mitchell, 166
Botanical Records of the Rocks, with Special Reference to the Early *Glossopteris* Flora ; Prof. A. C. Seward, 197 ; 449
Botany : Elementary, 647 ; General : A Laboratory Manual of, Emma L. Fisk and Ruth M. Addoms, 647 ; A Text-book of, G. M. Smith, and others, revised edition, 647 ; Systematic, A Text-book of, Prof. B. B. Swingle, 407
Bourne or Gypsey Flows, J. H. Brown, 159
Boyle as a Philosopher of Science, G. W. Spriggs, 33
Brazil, North-Eastern, Birds of, C. E. Hellmayr, 705
Brewing, Institute of, The Research Scheme of the, 315
Bricklaying, problems of, 925
Bristol University, Installation of Mr. Winston Churchill as Chancellor, 968
British : Academy, conferment of an honorary fellowship upon Prof. A. H. Sayce, 65 ; and French Associations at Havre, The, 355 ; Association : South Africa Meeting of the, 28 ; in South and East Africa, Sir Richard Gregory, 918 ; Prof. F. J. M. Stratton appointed acting general secretary of the, 998 ; Broadcasting Corporation, The Educational Work of the, 455 ; Cotton Industry Research Association, The, 590 ; Empire, A Tribute to the, Capt. A. T. Mahan, 592 ; Cancer Campaign, Work of the, 629 ; Forestry Conference, The Third, 1928, 321 ; East Africa, Meteorology in, A. Walter, 283 ; Honduras, British Museum Expedition to, T. A. Joyce, 964 ; Institute of Radiology, election of officers, 105 ; Museum : (Natural History) Additions to the, 207, 703, 853 ; J. Ramsbottom appointed keeper of the Botany department, 853, 883 ; G. J. Arrow appointed deputy keeper in the Entomology department, 853 ; Retirement of Dr. A. B. Rendle, 883 ; Rainfall, 1928, 718 ; Science Guild, a Resolution on the Constitution of the Royal Commission on the Civil Service ; and one urging the appointment of a Royal Commission on the Post Office, 701
Broadcasting : Educational, H. Lynton Fletcher, 322 ; in Denmark, P. O. Langballe, 30 ; in Japan, 885 ; Power Stations for, 885 ; Station at Brookman's Park, The, 492
Brooks's Law, R. Gurney, 107
Brucine, Strychnine and, A Link Between, H. Leuchs, 821
Budde Effect, The, in Bromine and Chlorine, G. B. Kistiakowsky, 161
Buffalo Fly (*Lyperosia exigua*), damage by the, in Northern Australia, 314
Bunsen Flames of Unusual Structure, F. A. Smith and S. F. Pickering, 775
Burfitt, Walter, prize of the Royal Society of N.S.W., award of the, to D. N. D. Royle, 314
Bushman : Languages, Comparative Vocabularies of, Miss D. F. Bleek, 224 ; Rock-drawings and Paintings in South Africa, 628
Butterflies, Wild Birds and : Dr. W. E. Collinge, 334 ; Prof. E. B. Poulton, 577

Calcareous Concretions in the Upper Marine Series, Singleton District, N.S.W., H. G. Raggatt, 395
Calcium : and Magnesium Carbonates in Water, Solubilities of, containing Carbon Dioxide, Frear and Johnston ; Kline, 247 ; Hydride, CaH_2, The Dissociation of, P. Remy-Cenneté, 826 ; Substratum in the Galaxy, The Possibility of Observing an Emission Spectrum of the, Y. Öhman, 179
Calendar : of Patent Records, 40, 76, 113, 165, 214, 250, 285, 323, 357, 393, 430, 465, 502, 562, 637, 673, 710, 744, 779, 824, 860, 895, 932, 968, 1005 ; Reform of the, 977 ; Simplification for the United States, Report of the National Committee on, submitted to the Secretary of State, Washington, August 1929, 977 ; Thirteen-Month, Compiled by Julia E. Johnsen, 977
California Sardine, F. N. Clark, 596
Californian : Aborigines, Sociology of the, Dr. W. D. Strong, 318 ; Echinoderms, L. Boone, 496
Callichthys littoralis, The Development of, Frances M. Ballantyne, 825
Cambridge : Philosophical Society, election of officers, 772 ; Cambridge University : Mineralogy at, 45 ; the Denman Baynes studentship divided between E. C. Bullard and R. M. Margoei, 164 ; award of the Wrenbury scholarship to L. J. V. Shepherd ; Miss A. S. Dale re-elected to the Michael Foster research studentship, 164 ; award of a studentship at Immanuel College to J. K. L. MacDonald ; awards from the Research Fund ; E. T. C. Spooner elected to a research fellowship at Clare College, 284 ; theses approved for research degrees, 284 ; D. Portway appointed University lecturer and G. S. Gough demonstrator in engineering ; Dr. E. K. Rideal appointed a member of the Board of Research Studies, 824 ; F. H. Garner appointed University lecturer in agriculture, A. S. Watt Gurney lecturer in forestry and director of the University farm, 356 ; W. S. Mansfield awarded the Busk studentship in aeronautics, 357 ; J. N. Goodier and H. S. Sayles awarded the John Winbolt prize, 429 ; election to fellowships of Trinity College ; E. P. Weller appointed bursar of Gonville and Caius College, 637 ; D. R. P. Murray re-elected Benn W. Levy research student, 673 ; E. G. Williams and F. L. Arnott elected Isaac Newton students, and P. I. Dee the Stokes student at Pembroke College ; an honorary doctorate conferred on Sir James Alfred Ewing, 743 ; R. F. Kahn awarded the Adam Smith prize ; W. H. Watson and Dr. W. L. Webster awarded the Clerk Maxwell scholarship ; S. Goldstein elected a fellow of St. John's College, 778 ; Sir James Jeans appointed Rede lecturer for 1930 ; Dr. R. A. Webb appointed University lecturer in pathology ; Dr. W. Shaw awarded the Raymond Horton-Smith prize for 1928–1929 ; J. M. Whittaker elected a fellow and lecturer and director of mathematical studies at Pembroke College, 860 ; Prof. H. Weyl appointed Rouse Ball lecturer, 895 ; C. F. A. Pantin appointed University lecturer in zoology ; J. E. E. Craster appointed University lecturer in geography ; Dr. F. P. Bowden elected a fellow of Gonville and Caius College, 931 ; C. P. Butler appointed first senior observer and W. Moss second senior observer at the Solar Physics Observatory ; W. B. R. King reappointed assistant to the Woodwardian professor of geology, 968
Canada : Department of Mines of, Annual Report, 156 ; Meteorological Service of, J. Patterson appointed director of the, 157 ; National Parks in, 703 ; Royal Society of, Annual Meeting of the, 110

Canadian : Hydro - Electric : Development, 498 ; Power Development, Recent Progress in, Dr. Brysson Cunningham, 130 ; School of Prehistory, Work of the, 104 ; Dr. H. M. Ami, 1003 ;
Canberra, Proposed Establishment of a National University at, 250
Cancer : Cosmic Rays and, Prof. J. Joly, 579 ; Immunity against, conferred on Animals by Phenolate Autovaccine, G. Tizzoni and G. De Angelis, 638 ; Radium and, 815 ; Research : 844 ; Committee of the University of Sydney, *Journal* of the, 385
Cannabis sativa L., Sudden Variations in the Leaf Form of, R. Savelli and N. Soster, 970
Cape Observatory, Report for 1928 of the, 244
Capillary Water in Rocks and Minerals, The, V. I. Vernadskij, 781
Carbohydrate : Content of : Detached Partially Shaded Leaves, R. Gane, 114; Foods, The, R. A. McCance and R. D. Lawrence, 635 ; Transformation in the Animal Organism, Prof. P. Albertoni, 738
Carbohydrates and their Digestion, 635
Carbon : Amorphous, S. Paramasivan, 707 ; An Isotope of, Mass 13, Dr. A. S. King and Prof. R. T. Birge, 127 ; Compounds, The Pyrolysis of, Prof. C. D. Hurd, 86 ; Dioxide : in Small Capillaries, Critical Temperature Measurements on, H. T. Kennedy, 161 ; Influence of, on the Vernal Awakening of the Snail, A. De Waele, 934 ; Filaments, Magnetic Reaction of, C. W. Marshall, 727 ; Industrial, Dr. C. L. Mantell, 537; Isotope, Mass 13, Further Evidence of the, Prof. R. T. Birge, 182 ; Molecule, The, Dr. R. C. Johnson and R. K. Asundi, 210 ; Monoxide : and Air, Temperatures of Ignition of Mixtures of, M. Prettre and P. Laffitte, 41; The Compressibility of, at 0° C. above 50 atmospheres, S. Goig, 431 ; Steels for Boiler Construction, Strength of, R. G. Batson and H. J. Tapsell, 161 ; the *Ka* line of, Measurement of, C. E. Howe, 216 ; The Microestimation of, and the Estimation of this Element in Arable Soil, M. Nicloux, 934
Carbonic Oxide-Oxygen Explosions, The Movements of Flame in, Prof. H. B. Dixon, 580
Carboniferous Rocks in the Hunter River District between Raymond Terrace and Scone, the Structural Geology of the, Prof. G. D. Osborne, 781
Cardiff, University College, appointments at, 779
Cardio-Vascular : Diseases since Harvey's Discovery, Sir Humphry Davy Rolleston, Bart., 613 ; System, The Pressure Pulses in the, Prof. C. J. Wiggers, 873
Carnegie : Endowment for International Peace, Annual Report of the Division of Intercourse and Education, 429 ; Institution of Washington : Activities of the, 384 ; Department of Terrestrial Magnetism, Annual Report, 157
Carnegie : Voyage of the, 68 ; Twenty-fifth Anniversary of Research Activities on the, 458 ; Loss of the, 883, 956
Carnmenellis Granite, The, P. K. Ghosh, 744
Carp, ' Knothead ', D. H. Thompson, 70
Cass, Sir John, Technical Institute, the Work of the, Rev. J. F. Marr, 673
Cassiopeæ, The Variable Star, 259.1928, J. Pagaczewski, 969
Casting, Influence of the Structure of the, on the Alterations Undergone at High Temperatures, A. Le Thomas, 861
Casuarina paludosa, Polarity in, T. T. Colquhoun, 896
Cat : The Bio-Psychology of the, 364 ; The Modern, her Mind and Manners : an Introduction to Comparative Psychology, Prof. Georgina Stickland Gates, 364
Catalysis, Industrial, Dr. E. F. Armstrong, 47
Catalytic Processes in Applied Chemistry, Prof. T. P. Hilditch, 47
Caterpillars : and Ants, Prof. J. W. Heslop Harrison and W. Carter, 424 ; Aquatic, H. S. Pruthi, 107
Catgut and its Sterilisation, Prof. W. Bulloch, Dr. L. H. Lampitt, and J. H. Bushill, 855
Cathode : Ray Oscillograph, Use of the, Prof. R. Whiddington, 114 ; Rays, Diffraction of, Prof. G. P. Thomson, 556
Caucasus, A Botanical Expedition to the, in 1929, R. Singer, 971
Caudina, Behaviour of, T. Zamanouchi, 738
Caulerpa, Reproduction in, R. Dostal, 780
Cave Excavation in the Near East, Miss D. A. E. Garrod, 957
Cedar Keys Bird Refuge, The, 553
Cellulose : Methylene Ether, New, Dr. F. C. Wood, 762 ; Structure of, A. Urquhart ; F. T. Pierce, 280
Cements, Limes and Plasters : their Materials, Manufacture and Properties, E. C. Eckel. Third edition, with chapters on Alumina Cements and High-strength Portlands, 439
γ Centauri, The Orbit of, W. H. van den Bos, 737
Centipedes, Amphibious, Dr. C. Crossland, 794
Central Activities, The Promotion of, by a Stimulant from the Central Organ, E. Steinach and H. Kun, 781
Cephalanthera, The Pollination of, M. J. Godfery, 933
XX Cephei, The Variable Star, J. Mergentaler, 969
Cercariæ in the Shan States, Possible Molluscan Hosts for, Dr. H. S. Rao, 209
Ceroplatinæ, The, with Descriptions of New Australian Species, F. W. Edwards, 395
Ceylon : Mammals of, W. W. A. Phillips, 209 ; Marine Biology in, Dr. J. Pearson, 742
Chart of the Development of Biochemistry, Physiology, and General Biology, Dr. J. Needham, 664
Chaulmoogric Acid, Synthesis of, from Hydnocarpic Acid, 109
CH-Band, The, at λ3143 and a New NH-Band at λ2530, Prof. T. Hori, 480
Chelsea Polytechnic, Courses at the, 860
Chemical : Biogenesis : Prof. J. Read, 426 ; and the Development of Secretion Cells, Dr. A. Leemann, 946 ; Elements, The Distribution of the, Prof. V. M. Goldschmidt, 15 ; Engineers, Institution of, *Transactions* of the, 1928, 887 ; Reactions, Effect of Water on, G. R. Gedye, 775 ; Technology, Inorganic, Prof. W. L. Badger and Prof. E. M. Baker, 537
Chemie in Natur und Wirtschaft, Kurzes Lehrbuch der, Prof. C. Oppenheimer und Prof. J. Matula. Zweite Auflage. Band 1 : Allgemeine Chemie, Prof. J. Matula ; Anorganische Chemie, Prof. C. Oppenheimer. Band 2 : Organische Chemie, Prof. C. Oppenheimer, 176
Chemistry : A School Certificate, G. H. J. Adlam, 980 ; and Mineralogy, An Etymological Dictionary of, Dr. Dorothy Bailey and Dr. K. C. Bailey, 789 ; and Monographs, 86 ; Analytical, Based on the Text of Prof. F. P. Treadwell. Translated, enlarged and revised by Prof. W. T. Hall, Vol. 2 : Quantitative Analysis. Seventh edition, 684 ; Applied : a Practical Handbook for Students of Household Science and Public Health, Prof. C. K. Tinkler and Helen Masters, Vol. 1. Second edition, 536 ; Applied, Reports of the Progress of, Vol. 13, 1928, 406 ; Colloid : Prof. T. Svedberg. Second edition, revised and enlarged in collaboration with A. Tiselius, 223 ; Theoretical and Applied, collected and edited by J. Alexander. Vol. 2 : Biology and Medicine, 609 ; Elementary Organic, A Concise Summary of, Dr. F. H. Constable, 536 ; Everyday, Prof. J. R. Partington, 715 ; for Students and Others, 715 ; in Daily Life, Dr. S. Glasstone, 224 ; Inorganic and Theoretical, A Comprehensive Treatise on, Dr. J. W. Mellor. Vol. 9, 757 ; of the Sugars, 291 ; Organic : Elementary Laboratory Experiments in, Prof. R. Adams and Prof. J. R. Johnson, 7 ; The Relation of, to Biology, Prof. G. Barger, 146, 234; Pharmaceutical, A Treatise on, Dr. J. C. Krantz, Jr., 943; Physical: A Class Book of, Prof. T. M. Lowry and Dr. S. Sugden, 367 ; Elementary, 365
Chemotaxis, The Phenomena of, in Connexion with the Choice of Food by Infusoria, L. Lozina-Lozinskij, 969
Child of Circumstance, The : the Mystery of the Unborn, Dr. A. Wilson, 297
Children, Three Minute Talks about, Estelle Cole, 407
Child's Conception of the World, The, Prof. J. Piaget. Translated by J. and A. Tomlinson, 686
Chile, Earthquake Conditions in, Prof. B. Willis, and others, 391
Chilean Earthquake of 1922, The, Dr. C. Davison, 391
China, Pleistocene Man in, 973
Chinese : Crab Naturalised in Europe, Dr. W. Wolterstorff, 596 ; Reptiles, C. H. Pope, 633

Chippewa Customs, Frances Densmore, 496
Chloride of Dimethylacrylic Acid, The Condensation of the, with Benzene, G. Darzens, 934
Chlorides of Certain Bivalent Elements, The Crystal Structure of the, L. Pauling, 898
Chlorine, Trebly Ionised, Structure of, S. C. Deb, 513
Chlorophyll Content and Rate of Photosynthesis, R. Emerson, 216
Chlorosis in Fruit Trees, Removal of, T. Wallace, 70
Chromium, Melting Point of, Dr. C. J. Smithells and S. V. Williams, 617
Chromobacterium, Two New Species of Bacteria belonging to the Genus, M. Grimes, 1006
Chromosomes: and Magnets, Y. Kuwada, and others, 354; Human, Prof. H. M. Evans and Dr. Olive Swezy, 819
Chromosphere, Altitude of the, in 1928, and Course of the Present Solar Cycle, G. Abetti, 862
Cinchona in the British Empire, Dr. J. M. Cowan, 881
Cinematography, Amateur, Capt. O. Wheeler, 649
Cinnabar Ore Deposit in the Urals, A New, J. Argentinovskij, 969
Circuit Analysis, Operational, Prof. V. Bush. With an Appendix by Prof. N. Wiener, 538
Cis-trans Ethylenic Saturated and Acetylenic Acids, A Relation Between the Boiling Point and the Molecular Structure of, Bourguel, 77
City and Guilds of London Institute, Report for 1928, 357
Civil Service: the Organisation, etc., of the Scientific Department of the, 205; The Royal Commission on the, 565, 590; the Status and Functions of Scientific and Technical Experts engaged in the, 767
Cladocera, Pelagic Freshwater, Dr. R. Woltereck, 773
Clausius, the Virial of, The Generalisation of, S. Ray, 78
Climate: a Handbook for Business Men, Students and Travellers, Dr. C. E. P. Brooks, 982; and Acclimatisation, Sir Aldo Castellani, 629
Climates, Past, Dr. G. C. Simpson (Alexander Pedler Lecture), 988
Clypeaster, A Four-rayed, I. Taki, 855
Coal: Iron, and World Peace, 169; Reserves of China, K. H. Lih, 301; The Writer of the Article, 302; Scientific Utilisation of, Dr. C. H. Lander, 464
Cobalt: Chloride and its Variations, The Absorption Spectrum of, P. Vaillant, 934; Photoelectric and Thermionic Emission from, Effects of a Crystallographic Transformation on the, A. B. Cardwell, 603
Cocoa, The Theosterols of, H. Labbe, H. de Balsac, and R. Lerat, 1007
Coconut: The Original Home and Mode of Dispersal of the, Dr. A. W. Hill, 133, 507; Sir R. A. S. Paget, Bart., 508
Codling: Moth, Control of the, 107; of the North Sea, M. Graham, 352
Collagen Substances, Modifications of the, under the Action of the Radiation from Radioactive Bodies, J. Loiseleur, 115
Colloid Chemistry: and Biology, 609; of Protoplasm, The, Prof. L. V. Heilbrunn, 173
Colloidal Gold, Prof. P. P. von Weimann, 668
Colloids, Theoretical Treatment of, The Physical and Chemical Points of View in the, Prof. J. N. Mukherjee, 420
Cold Wave in India, February 1929, Probable Origin of the, Dr. S. C. Roy and G. Chatterji, 579
Colds: Common, Causes and Preventive Measures, Dr. L. Hill and M. Clement, 435
Colombia, Northern, Miocene of, F. M. Anderson, 71
Colombo Museum, Report of, for 1927, Dr. J. Pearson, 422
Colonial: Development: and the Scientific Worker, 433; Fund, Appointment of a Committee in Connexion with the, 243; Office Appointments, 157, 458, 595, 960
Colophon (Coleoptera), A Study of the Genus, K. H. Barnard, 78
Color Photography, Practical, E. J. Wall, 649
Colour: and Chemical Constitution (26), J. Moir, 78; and Colour Theories, Dr. Christine Ladd-Franklin, 686; Sensation, Fechner's Law in, The General Applicability of, Prof. W. Peddie, 791
Combabet, Geology of the Region Comprised Between the, and the Eastern Luvisi, H. Lagotala, 394
Combustion in Electrical Discharges, G. I. Finch and D. L. Hodge, 160
Comet, Reported New, E. F. Carpenter, 998; Schwassmann-Wachmann, 631
Comets: Neujmin and Forbes, 495; Orbits of Neujmin's and Forbes's, *b* 1929 and *c* 1929, 351; Periodic, F. Baldet, 32; Two New, 317
Comma Butterfly in England, The: Dr. F. S. Dawe; N. D. Riley, 653; 770, 853
Complement Fixation, Electric Charge in its Relation to, Major H. C. Brown and Dr. J. C. Broom, 794
Complex Compounds, Structure of, L. Pauling, 929
Comte, Auguste, Thinker and Lover, Jane M. Style, 721
Concrete Poles, The Use of, W. T. Taylor, 275
Conditioned Reflexes: Lectures on Twenty-five Years of Objective Study of the Higher Nervous Activity (Behaviour) of Animals, Prof. I. P. Pavlov. Translated by Dr. W. H. Gantt, with the Collaboration of Prof. G. Volborth, 400
Congo, Lower, The Geology of the, L. Duparc, 78
Conocephalum conicum, A. G. Lowndes, 513
Contact-Metamorphic Structures in Technical Processes, D. Beliankin and M. Bezborodov, 781
Continental Drift, Prof. A. Holmes, 246
Continents and Oceans, Dr. G. C. Simpson, 837, 948
Cook, Capt., a Memorial Plaque to, placed in Vancouver Cathedral, 208
Co-operation: the Task of the Museums Association, Sir Henry A. Miers, 274
Copals and Damars, A. F. Suter, 392
Copepods of the *Terra Nova* Expedition, G. P. Farran, 820
Copley Medal of the Royal Society, The, 815
Copper: Butterfly, the Large, 551; Copper Deposits of Michigan, B. S. Butler and W. S. Burbank, 633; The Open-air Corrosion of, W. H. J. Vernon and L. Whitby, 430
Coral: Reef Problem, The, Prof. W. M. Davis, 831; Reefs: Theories of, Prof. W. M. Davis, 246; Origin of, J. A. Steers, 831
Corbicula, Asiatic Species of, Dr. B. Prashad, 387
Corona: Attempts to Photograph the, without an Eclipse, A. Hnatek, 459; The Spectrum of the, E. M. Lindsay, 94
Corrodibilities of Ferrous and Non-ferrous Metals and Alloys, The Relative, Dr. J. N. Friend, 466

CORRESPONDENCE.

Abra (=*Syndosmya*) *alba*, *Donax vittatus*, Severe Environmental Mortality among, and other Organisms off the Lancashire Coast, Prof. J. H. Orton, 911
'Absolute', The, and 'Relative', W. W. L., 126
Acetaldehyde, The Oxidation of, by Oxygen, E. J. Bowen and E. L. Tietz, 914
Acetylene: Combustion of, Prof. W. A. Bone, 839; The Homogeneous Oxidation of, G. B. Kistiakowsky and Dr. S. Lenher, 761
Adaptation, Prof. A. Meek, 509; J. T. Cunningham, 617
Adaptations and the Influence of Light on Animal Tissues, M. Perkins, 759
Adrenal Cortex, A Function of the, Prof. Swale Vincent and J. H. Thompson, 445
Agropyrons, Chromosome Numbers in the, F. H. Peto, 181
Alphabets, The Origin of, Sir R. A. S. Paget, Bart., 228
Animal Remains, Preservation of, Dr. J. Parkinson, 56
Approximate Calculation, Rapid, R. d'E. Atkinson, 94
Aquaria for Rearing Minute Organisms requiring Running Water, C. Dover, 336
Argon, Trebly Ionised, Spectrum of, D. S. Jog, 303
Arsenic, Doubly Ionised, Spectrum of, A. S. Rao and Dr. A. L. Narayan, 229
Aurora: Rays, Sunlit, The Spectrum of, as compared with the Spectrum of Lower Aurora in the Earth's Shadow, Prof. C. Størmer, 263; Spectrum, Variations of Intensity Distribution of the, and the possible Influence of Sunlight, Prof. L. Vegard, 947
Australoid Element in the Korannas, Dr. R. Broom, 507

Balloons for Upper Air Work, G. Chatterjee, 793
Benzol, Fluorescence of, Raman Spectrum and, C. V. Shapiro, 372
Biological Research, Statistics and, Dr. E. S. Pearson, 615
Birds, Sexual Behaviour in, E. Selous, 761
Bopyridæ, Mode of Feeding of the, B. W. Tucker, 985
Butterflies, Wild Birds and, Prof. E. B. Poulton, 577
Calcium Substratum in the Galaxy, The possibility of observing an Emission Spectrum of the, Y. Öhman, 179
Cancer, Cosmic Rays and, Prof. J. Joly, 579
Carbon : An Isotope of, Mass 13, Dr. A. S. King and Prof. R. T. Birge, 127 ; Filaments, Magnetic Reaction of, C. W. Marshall, 727 ; Isotope, Mass 13, Further Evidence of the, Prof. R. T. Birge, 182
Cellulose Methylene Ether, New, Dr. F. C. Wood, 762
Centipedes, Amphibious, Dr. C. Crossland, 794
Charcoal, The Adsorption of Organic Acids by, C. Fromageot, 412
CH-Band, The, at λ3143 and a new NH-Band at λ2530, Prof. T. Hori, 480 ; Chemical Biogenesis and the Development of Secretion Cells, Dr. A. Leemann, 946 ; Prof. J. Read, 987
Chlorine, Trebly Ionised, Structure of, S. C. Deb, 513
Chromium, Melting Point of, Dr. C. J. Smithells and S. V. Williams, 617
Coal Reserves in China, K. H. Lih, 301 ; The Writer of the Article, 302
Coconut, The Original Home and Mode of Dispersal of the, Dr. A. W. Hill, 133, 507 ; Sir R. A. S. Paget, 508
Colloidal Solutions and Gels, The Scattering of Light in, K. Krishnamurti, 690
Comma Butterfly in England, The, Dr. F. S. Dawe ; N. D. Riley, 653
Conocephalum conicum, A. G. Lowndes, 513
Continents and Oceans, Dr. G. C. Simpson, 837, 948
Corona, The Spectrum of the, E. M. Lindsay, 94
Cosmic Rays and Cancer, Prof. J. Joly, 579
Courtship Displays of Birds, V. C. Wynne-Edwards, 302
Cronartium, A New Species of, from the Himalayas, Dr. K. Bagchee, 692
Crustacea, Heterogenic Growth in the Appendages of, J. T. Cunningham, 14
Crystal, Symmetry Axis of a, Method of determining the position of the, by means of X-rays, W. Linnik, 946
Crystalline Tripeptid, A, from Living Cells, Sir F. Gowland Hopkins, 445 ; Dr. M. Dixon and N. U. Meldrum, 512
Crystals : Compressibility of, Dr. R. F. Mehl and R. H. Canfield, 478 ; Floating on a Saturated Aqueous Solution, Electrical Phenomena of, N. Katoh, 653
Dew : Does it Rise or Fall ? Sir Herbert Maxwell, Bart., 412, 725 ; Prof. J. B. Cohen, 482, 725 ; E. A. Martin, 513 ; Dr. G. C. Simpson, 578, 725
Diamagnetism : Anomalous, Sir C. V. Raman, 412 ; Influence of Particle Size on, V. I. Vaidyanathan, 762
Dielectric Constant of the Ground, A Determination of the, J. A. Ratcliffe and W. F. B. Shaw, 617
Dinosaurian and Mammalian Remains in South India, Prof. C. R. Narayan Rao, 227
Disease-producing Viruses, Nature of, Dr. J. J. Davis, 267
Diseases and Weeds in a Forest Nursery, Control of, A. E. Muskett, 481
Dragonflies in Folk-Lore, Dr. W. Maldwyn Davies ; Dr. W. T. M. Forbes, 55
Earth, Rotation of the, and Magnetostriction, A. H. R. Goldie, 303
Earthquake : Sounds Heard at Great Distances, A. Thomson, 687 ; Dr. F. J. W. Whipple, 688 ; South of Newfoundland, The, and Submarine Canyons, Prof. J. W. Gregory, 945
East African Archæology, L. S. B. Leakey and J. D. Solomon, 9
Echinus esculentus, Regeneration of Spines in, H. C. Chadwick, 760
Electric : Arc, Motion of an, in a Magnetic Field under Low Gas Pressure, R. Tanberg, 371 ; Charge in its relation to Complement Fixation, Major H. C. Brown and Dr. J. C. Broom, 794
Electromagnetic Waves, Penetration of Rocks by, Prof. A. S. Eve, Dr. D. A. Keys, and F. W. Lee, 178
Electron : Collisions with Molecules and Resultant Quantum Losses, Prof. R. Whiddington, 758 ; Properties of the, R. D. Kleeman, 728 ; The Charge of an, Prof. A. S. Eddington, 840
Electrons, Scattering of, by Gold, N. F. Mott, 986
Emission von Serienlinien, Weitere Beobachtungen über die Dissymmetrie der, Prof. J. Stark, 946
Enantiomers, The Physical Identity of, Dr. A. N. Campbell, 792
" Encyclopædia Britannica ", The, Dr. H. A. Baylis, 987
Engineering, Science and, H. P. Vowles, 618
Fechner's Law in Colour Sensation, The General Applicability of, Prof. W. Peddie, 791
Forest Nursery, Control of Diseases and Weeds in a, A. E. Muskett, 481
Forestry Research in India, The Writer of the Article, 840
Foveal Region of the Retina, Influence of the Para-Foveal Regions on the, Dr. F. W. Edridge-Green, 877
Fraunhofer Lines, Faint, A Possible Origin of, Daulat Singh Kothari, 90
Frenkel Adsorption Isotherm, The, F. J. Wilkins and A. F. H. Ward, 482
Gas Discharges, Spiral Forms in, Dr. S. P. McCallum and W. T. Perry, 984
Gases, Incoherent Scattering in, Further Investigations on, F. Rasetti, 93
Glasses transparent to Ultra-violet Radiation, A. R. Wood and M. N. Leathwood, 441
Golgi Body and Vacuome, Prof. D. R. Bhattacharya and Dr. R. S. Das, 692
Graptolite Centenary, Prof. W. W. Watts, 877
Grass Seeds, Vitamin Contents of, from Treated Plots, Dr. M. I. Rowlands, 760
Growth-gradients and the Axial Relations of the Animal Body, M. Perkins, 299
h, c, and e^2, Relationship between, Dr. W. N. Bond, 408
He_2 Rotation Terms, Properties of the, Prof. W. E. Curtis and A. Harvey, 12
Heisenberg's Indetermination Principle and the Quantum, Prof. G. E. M. Jauncey, 57
Helium Band Lines, Fine Structure in the, Dr. G. S. Monk and Prof. R. S. Mulliken, 91
Heterodyne Null Method of Measuring Dielectric Constant, The, Prof. P. N. Ghosh and P. C. Mahanti, 13
High Frequency : Currents, An Absolute Method of Measuring, Dr. R. L. Smith Rose, 651 ; Discharges, Striations in, K. A. Mackinnon and Prof. J. K. Robertson, 55
Homology, Isomorphism and, Sir P. C. Rây, 480
Hydrogen : A New Connexion between the Absorption Spectrum of, and the Many Lined Spectrum, Prof. O. W. Richardson, 408 ; Atom in the Electric Field, Asymmetry in the Radiation from the, Prof. J. Stark, 125
Hydrolytic Adsorption at Colloid Surfaces, S. W. Pennycuick, 987
Iceberg Detection, Prof. H. T. Barnes, 337
Icebergs in a High Latitude, R. W. Gray, 479
India : Meteorology in, Dr. C. W. B. Normand ; The Writer of the Article, 335 ; Probable Origin of the Cold Wave in, February 1929, Dr. S. C. Roy and G. Chatterji, 579
Infra-Red Absorption in Organic Compounds, Fine Structure of, and the Raman Effect, Dr. R. B. Barnes, 300
Intermediate Compound, An, having a Simple Cubic Lattice, A. Ôsawa, 14
Ionisation Potentials and Conductivities of Metals, Prof. B. B. Ray and D. P. R. Chaudhuri, 512
Ionising Radiation, Natural, and Rate of Mutation, Prof. E. B. Babcock and Prof. J. L. Collins, 227
Ions in Gases, The Mobility of, R. J. Van de Graaff, 10
Isomorphism and Homology, Sir P. C. Rây, 480
Kenya, Biology of Lakes in, Penelope M. Jenkin, 574
Korannas, Australoid Element in the, Dr. R. Broom, 507
Laminariæ, An Iodine Liberator from, Dr. G. Lunde and K. Closs, 578
Lankester's ' Gregarine ' from the Eggs of *Thalassema neptuni*, Prof. D. L. Mackinnon and H. N. Roy, 877
Lanthanum, New Bands in the Spectrum of, Oxide of, G. Piccardi, 129
Laterite, Fossil, from Southern Queensland, W. H. Bryan, 512

Lead : Molten, Handling, Capt. E. H. Gregory, 760 ; The Second Spark Spectrum of, A. S. Rao and Dr. A. L. Narayan, 794
Lightning, Progressive, Prof. C. V. Boys, 54
Liquid-Solid Interface Tension, Dr. M. Loewenthal, 301
Littorina littorea Linn., A Habit of the Common Periwinkle, D. P. Wilson, 443
Lockyer, Norman, and the Total Solar Eclipse of 1875, Sir Arthur Schuster, 838 ; Prof. H. Dingle, 839
Lophius piscatorius, Feeding Habits of the Angler-fish, H. C. Chadwick, 337
Lorentz Electron, The Motion of a, as a Wave Phenomenon, Prof. A. M. Mosharrafa, 726
Lo Surdo Fields, Production of High, Prof. Y. Ishida and S. Hiyama, 129
Low Velocity Electrons, Action of, on Micro-organisms, Dr. D. A. Wells, 983
Magnesium Oxide, Band Spectrum of, Prof. P. N. Ghosh, B. C. Mookerjee, and P. C. Mahanti, 303
Magnetostriction of Dimagnetic Substances in Strong Magnetic Fields, Dr. P. Kapitza, 53
Mammalian Life in High Latitudes, R. W. Gray, 228
Manganese : A High-Temperature Modification of, E. Persson and E. Öhman, 333 ; High Temperature, Allotropes of, Dr. Marie L. V. Gayler, 840
Mathematical Physics, Decay Problems in, Dr. M. Strutt, 230
Medical Works, Distribution of, William Heinemann (Medical Books), Ltd., 728
Mendelian Mutants, Fossil Records of, Dr. C. Diver, 183
Mercury Line 1849–57 ($1^1S_0 - 2^1P_1$), Behaviour of the, Prof. A. T. Williams, 985
Metals : Conductivities of, Ionisation Potentials and, Prof. B. B. Ray and D. P. R. Chaudhuri, 512 ; Passivity of, Optical Investigations of the, L. Tronstad, 373
Meteorology in India, Dr. C. W. B. Normand ; The Writer of the Article, 335
Mimicry, Dr. G. D. Hale Carpenter, 183
Molecular Spectra and Molecular Structure, Profs. W. E. Garner and J. E. Lennard-Jones, 762
Muscular Sense, Subjective Demonstration of the Existence of the, Prof. D. F. Fraser-Harris, 794
Natural : History and Folk-Lore, C. Oldham ; L. Rowland, 229 ; Selection, Prof. E. W. MacBride, 225 ; Prof. W. Garstang, 410 ; J. B. S. Haldane, 444 ; Prof. E. W. MacBride, 689
Nerve Centres, Mechanism in, Prof. A. Forbes, 911
Newton's "System of the World", The translator of, Prof. F. Cajori, 513
Nickel Vapour, The Number of Excited Atoms and the Absorption Spectrum of, Prof. A. T. Williams, 373
Nitrogen : Afterglow, The, Dr. E. J. B. Willey, 443 ; Solid, The Crystal Structure of, Prof. L. Vegard, 267, 337 ; Spectrum of, Alternating Intensities in the, F. Rasetti, 792 ; Tetroxide, Rate of Dissociation of, Prof. A. R. Olson and C. E. Teeter, Jr., 444
Noble Gases in Vacuum Tube Discharges, Appearance of, D. Dooley, 372
Nor'westers, Origin of, Dr. S. C. Roy and G. Chatterji, 481
Oceans, Continents and, Dr. G. C. Simpson, 837, 948
Ocinebra erinacea, Habitats and Feeding Habits of, Prof. J. H. Orton, 370
Œnothera, A Haploid, Prof. R. R. Gates, 948
Ore : Deposits, Ore-lead and Rock-lead and the Origin of, Prof. A. Holmes, 477 ; -lead and Rock-lead and the Origin of certain Ore Deposits, Prof. A. Holmes, 477
Organic Vapours, High-frequency Discharge in, Prof. P. N. Ghosh and B. D. Chatterjee, 654
Oscillating Arc, A Phenomenon of the, Prof. W. Cramp and A. P. Jarvis, 913
Ovarian Hormones, The, Dr. F. H. A. Marshall ; The Writer of the Article, 94
Oxides of Praseodymium, Neodymium, and Samarium, Band Spectra of the, Prof. G. Piccardi, 618
Oxygen : and Nitric Oxide, Heat of Adsorption of, on Charcoal, H. I. Bull and Prof. W. E. Garner, 409 ; Group, Elements of the, Low Atomic Energy Levels for, Prof. J. C. McLennan and M. F. Crawford, 874 ; The Isotopes of, Prof. R. T. Birge, 13
Oyster : Culture in Malaya, C. Dover, 264 ; -drills on English Oyster-beds, The, Prof. J. H. Orton and C. Amirthalingam, 298
Oysters : Hermaphrodite, Prof. P. Pelseneer, 14 ; Monœcious, T. C. Roughley, 793
Ozone, Photosensitised Decomposition of, Prof. A. J. Allmand and J. W. T. Spinks, 651
Palæozoic Glaciation : Late, in South Africa, Palæobotanical Evidence for the Age of the, Dr. J. Walton ; Dr. H. Dighton Thomas, 614 ; The Late, Dr. G. de P. Cotter, 723
Paramagnetic Salts, Fused, L. A. Welo, 575
Parasitic Autotomy in Worms and its possible Significance, Mabel Fullegar, 792
Patents, Invalid, The Grant of, C. Romer, 874 ; Dr. N. R. Campbell ; The Writer of the Article, 875
Periodic Precipitations and Diffusion, Prof. H. Ryan and R. J. Doyle, 762
Phosphorus Vapour, Optical Excitation of, Miss A. Jakovlev and A. Terenin, 337
Photosynthesis, The Energetic Efficiency of, Dr. R. Wurmser, 912
Phototropy in Inorganic Compounds, E. Lakshminadha Rao, K. Varahalu, and M. V. Narasimhaswami, 303
Physics and Biology, The Problem of Form in, N. Rashevsky, 10
Pisum, A Chromosome Ring in, Eva Richardson, 578
Planaria alpina in Lithuania, Prof. P. B. Sivickis, 579
Plant : Cell Membrane, The Permeability of, to Sugar, Prof. R. S. Inamdar and K. V. Varadpande, 875 ; Cytology, New Fixatives for, L. La-Cour, 127
Plasmatic Membrane, Electrical Excitation and the possible Structure of the, Prof. H. B. Dixon and T. A. Bennet-Clark, 650
Polarised Light, Reflection of, A. C. G. Beach, 373
Potential Temperature in the first 25 Kilometres over the Northern Hemisphere, Distribution of, Dr. K. R. Ramanathan, 509
Primates, the Order, The Subdivision of, Prof. G. Elliot Smith, 876
Proton, Electron, and Helium Nucleus, The Relative Masses of the, E. E. Witmer, 180
Puccinia graminis, Nuclear Association in the Æcium of, Dr. W. F. Hanna, 267
Quantum Theory : and Special Relativity, Dr. M. S. Vallarta, 336 ; The, and the Absorption of Light, Prof. J. Frenkel, 758
Rainfall : Attempts to Induce, C. W. Jeffries, 482 ; March, of North-West India and Agra Upper Winds in December-January, M. V. Unakar, 618
Raman : Effect : and Electrolytic Dissociation, I. Ramakrishna Rao, 762 ; for X-rays, The, Prof. D. Coster, I. Nitta, and W. J. Thijssen, 230 ; from Powdered Crystals, A. C. Menzies, 511 ; Prof. R. Bär, 692 ; in Carbon : Dioxide, Prof. P. N. Ghosh and P. C. Mahanti, 92 ; Disulphide, The, A. S. Gavesan and S. Venkateswaran, 57 ; in Gases and Liquids, Prof. P. N. Ghosh and P. C. Mahanti, 230 ; Lines, Influence of Temperature on, Y. Fujioka, 11 ; Spectra : and Ultra-violet Absorption, A Relation between, A. Langseth, 92 ; in Atmospheres surrounding Metallic Arcs, B. Venkatesachar and L. Sibaiya, 838 ; Spectrum and Fluorescence of Benzol, C. V. Shapiro, 372
Rearing Experiments with Starfish and Obstetric Toads, Prof. E. W. MacBride, 727
Red Cyanogen Bands, Vibrational Quantum Analysis of, R. K. Asundi and J. W. Ryde, 57
Relativity, Special, Quantum Theory and, Dr. M. S. Vallarta, 336
Retina, Foveal Region of the, Influence of the Para-Foveal Regions on the, Dr. F. W. Edridge-Green, 877
Rhodesian Mining, Early, and Zimbabwe, Prof. J. W. Gregory, 723
Rickets-producing Factor in Cereals, Nature of the, L. Mirvish, 410
Rostro-carinates, Geological Age of the, J. Reid Moir, 373
Rubber, The Swelling of, P. Stamberger and C. M. Blow, 13
Science : and Engineering, H. P. Vowles, 618 ; and Parliament, J. H. Coste, 728

Sea-Urchins on the Foreshore in Britain, Occurrence of, C. C. Hentschel; D. M. Reid, 226; C. N. Bromehead, 373
Selenium (Se^{++}), Second Spark Spectrum of, Prof. D. K. Bhattacharjya, 229
Solar Eclipse, The Total, at Iloilo on May 9, Dr. R. L. Waterfield, 177
Sounding Dust Tube, New Phenomena in a, Prof. E. N. da C. Andrade and S. K. Lewer, 724; E. J. Irons, 914
Space-time, Curvature Radius of, New Determination of the, Dr. L. Silberstein, 179
Spectra, Isotope Effect in, and Precise Atomic Weights, W. F. Giauque, 265
Spinning Target X-ray Generator, A, Dr. A. Müller, 128
Statistics: and Biological Research, Dr. R. A. Fisher, 266; Dr. E. S. Pearson, 615; in Biological Research, "Student", 93; Prof. Karl Pearson, 183
Sun, Total Eclipse of the, at Alor Star, Kedah, on May 9, Observations of the, Dr. J. Jackson, 90
Sunrise on the Moon, Kinematographic Record of, R. F. Arnott, E. G. F. Arnott, A. L. Bennett, and Prof. J. Q. Stewart, 56
Sun's Atmosphere, Turbulence in the, W. H. McCrea, 442
Sunspots and Pressure, M. V. Unakar, 11
Super-cooled Water, Dr. L. Hawkes, 225
Tahitian Coral Reefs, Recession and Age of the, Dr. C. Crossland, 576; H. Williams, 727
Thermionic Valve, Use of the, in Measurements of Ionisation Currents, J. A. C. Teegan, 91
Tracheal Respiration in Insects, A Theory of, V. B. Wigglesworth, 986
Tsetse Flies, Dipterous Parasites of, Prof. T. D. A. Cockerell, 693
Tuning-fork, the Frequency of a, Effect of Atmospheric Pressure on, Y. Namba, 511
Ultra-Violet Light, Lethal Action of, on Micro-organisms in a High Vacuum, Dr. D. A. Wells, 693
Universities' Library for Central Europe, C. Fuller, 576
Upper Atmosphere, The Tides of the, and the Heights of Meteors, J. Egedal, 913
UZ Persei, The Long Period Variation of, W. Zessewitsch, 93
Vacuum Spark Spectra in the Extreme Ultra-Violet down to 100 A, B. Edlén and A. Ericson, 688
Variations, The Origin of, Dr. E. J. Allen, 128; A. G. Lowndes, 129
Vibrating Air Column at High Frequency, S. K. Crews and F. C. Hymas, 793
Vitamin B, Prof. R. A. Peters, 411
Waller, Dr. Augustus, and Patents, Mary D. Waller, 654
Wave Electron, A Lantern Slide Model of the, Prof. S. R. Milner, 876
Weather Forecasting, Empirical Factors in, W. Trotter, 616; J. S. Dines, 726
West Indian Biota in New Caledonia, Prof. T. D. A. Cockerell, 615
Whales, Growth and Longevity of, N. A. Mackintosh, 302
Wild Birds and Butterflies, Dr. W. E. Collinge, 334; Prof. E. B. Poulton, 577
Witchcraft and the Black Mass, H. W. Chapman; The Reviewer, 693
Wool: Adsorption of Water by, J. B. Speakman, 411; The Perfect Elasticity of, J. B. Speakman, 948
X-ray: Absorption Edges, The Fine Structure of, Prof. D. Coster and M. Wolf, 652; Effect, A New, Sir C. V. Raman and P. Krishnamurti, 53; Diffraction by Plane Gratings, J. A. Prins, 370
X-rays, Diffraction of, by Two-dimensional Crystal Lattice, Prof. W. L. Bragg, 125
Zinc Crystals, Single, The Electromotive Behaviour of, M. Straumanis, 56
Zoological Nomenclature, Dr. C. W. Stiles, 265, 445

Corsica, Geological Observations in (4), E. Parejas, 43
Cosmic: Radiation, Secondary, D. Skobeltzyn, 34; Rays and Cancer, Prof. J. Joly, 579
Cosmical: Magnetic Phenomena (Rouse Ball Lecture), Prof. S. Chapman, 19; Physics, Some Problems of, Solved and Unsolved, Lord Rayleigh, 146, 185
Cottons, Punjab-American, Non-Dehiscence of Stamens in, T. Trought, 17
Courtship Displays of Birds, V. C. Wynne-Edwards, 302
Couvade, The Custom of, W. R. Dawson, 790
Cowell Method of Computing Perturbations, The, Dr. G. Stracke, 423
Crab-marking, 667
Craftsmanship in Modern Industry, 253
Crankshafts, Stiffness of, H. Constant, 320
Crimea, Absence from the, of Some Elements of the Lepidopterous Fauna, N. Kusnezov, 394
Cronartium, A New Species of, from the Himalayas, Dr. K. Bagchee, 691
Crop Production, The Application of Science to: an Experiment carried out at the Institute of Plant Industry, Indore, A. and Gabrielle L. C. Howard, 974
Crossing-over, Effect of Genes on, Serebrovsky, Ivanova, and Ferry, 928
Crustacea Brachyura of the Percy Sladen Trust Expedition to the Abrolhos Islands, Report on the, S. K. Montgomery, 933
Crystal: Decomposition in a, Dr. J. Colvin and Hume, 891; Method of Determining the Position of the Symmetry Axis of a, by means of X-rays, W. Linnik, 946; Structure and Chemical Constitution: a General Discussion held by the Faraday Society, March 1929, 219
Crystalline: Form, Importance of, in the Formation of Solid Solutions (5), A. Ferrari, A. Celeri, and F. Giorgi, 167; Plates, The Directions of Extinction of an Ensemble of Two Parallel, G. Cesaro, 934; Tripeptid from Living Cells, A, Sir F. Gowland Hopkins, 445
Crystallisation, Dr. F. H. Maberley, 247
Crystallochemistry, F. I. G. Rawlins, 219
Crystals: Compressibility of, Dr. R. F. Mehl and R. H. Canfield, 478; floating on a Saturated Aqueous Solution, Electrical Phenomena of, N. Katohr, 653; Liquid, and Chemical Constitution, D. Vorländer, 963; The Imperfections of, F. Zavicky, 216
Cyclopteropsis (Pisces, Cyclopteridæ), The New Genus, from the Okhotsk Sea, V. K. Soldatov and A. M. Popov, 358
Cyclostomes, Experimental Embryological Investigations on the, S. Ranzi (1), 862
Czecho-Slovak Agricultural Academy, Prof. F. A. E. Crew elected a foreign member of the, 157

Dahlias, Cultivated, Origin of, W. J. C. Lawrence, 890
Dairy Bacteriology, Prof. B. W. Hammer, 685
Dakota, Black Hills of, Mineral Wealth of the, J. P. Connolly and C. C. O'Harra, 319
Daphnias, Spontaneous Movements of, A. N. Ivanov and A. Tsvetkov, 324
Darwinism and Social Ethics, Bishop of Exeter, 217
d'astronomie, Cours. Tome 3: Astrophysique, Prof. J. Bosler, 49

DEATHS.

Allen (Dr. E. W.), 994
Andoyer (Prof. H.), 102
Andrews (W. S.), 102
Austin (Prof. L. S.), 994
Balfour (Sir Graham), 732
Bateman (Sir Alfred), 382

Spencer (Sir W. Baldwin), 154, 347
Terry (Prof. E. M.), 240
Thomas (M. R. Oldfield), 101
Thompson (Sir Edward Maunde), 455
Viljoen (Dr. W. J.), 154
Wager (Dr. H.), 848, 953
von Welsbach (Ritter), Karl Auer, 382
Wood (Prof. T. B.), 800, 813
Yamasaki (Prof. N.), 455, 994
Zsigmondy (Prof. R.), 520, 845

Dengue, The Virus of, G. Blanc and J. Caminopetros, 826
Desert Plants and Water, 293
Determinants, The Theory of, Matrices and Invariants, Prof. H. W. Turnbull, 262
Devonshire Association, Annual Meeting of the, 205
Dew : Does it Rise or Fall ? : Sir Herbert Maxwell, Bart., 412, 725 ; Prof. J. B. Cohen, 482, 725 ; E. A. Martin, 513 ; Dr. G. C. Simpson, 578, 725
Diamagnetism : and Space Charge Distribution, E. C. Stoner, 114 ; Anomalous, Sir C. V. Raman, 412 ; Influence of Particle Size on, V. I. Vaidyanathan, 762
Diamond : a Descriptive Treatise, Dr. J. R. Sutton, 406
Diazoaminobenzene, Action of Acids on, J. C. Earl, 898
Diazo-hydrates : Reactions of the, D. Bigiavi, 674 ; Reduction of Normal, A. Angeli and Z. Jolles, 970 ; The Constitution and Reactions of the, A. Angeli, 638
Dibranchiate Cephalopods of Japanese Waters, Dr. M. Sasaki, 392
Dichloramine, R. M. Chapin, 281
Dielectric : Constant of the Ground, A Determination of the, J. A. Ratcliffe and W. F. B. Shaw, 617 ; Constants of some Organic Liquids, Variation of the, with Frequency in the Range 1 to 10^3 Kilocycles, R. W. Lunt and M. A. G. Rau, 825 ; Loss in Electrolyte Solutions in High Frequency Fields, W. T. Richards and A. L. Loomis, 603
Diesel-electric Power Station, A Floating, 68
Diethyl : Pentasulphides, G. R. Levi and A. Baroni, 167 ; 359 ; Triselenide, Sulpho-diselenide, and Selenodisulphide, G. R. Levi and A. Baroni, 638
Differential-dilatometer, An Improved, M. Haas and D. Uno, 430 ; Equations and their Applications, An Elementary Treatise on, Prof. H. T. H. Piaggio, 683
Dihydroperillamine, Action of Nitric Acid on, W. Williams, 897
Dilute Solutions, The Foundations of the Theory of, Papers on Osmotic Pressure, by J. H. Van 't Hoff ; and on Electrolytic Dissociation, by Svante Arrhenius, 536
Dinas, Chemical Degeneration of, D. Beliankin, 969
Dinosaurian and Mammalian Remains in South India, C. R. Narayan Rao, 227
Dicœcious Angiosperms, The Chromosomes of some, Ruth H. Lindsay, 603
Diogenes : or the Future of Leisure, C. E. M. Joad, 685
Dioptric Apparatus, The Beam given by, W. M. Hampton, 77
Diphasic Sex Cycle, Mechanism of the, B. P. Wiesner, 826
Diphenyl Derivatives, Optical Activity of, F. Pufahl, 929
Diphtheric Toxin, Production of a very Active, G. Ramon, 896
Diptera of Patagonia and Southern Chile, 596
Dipterous Parasites of Tsetse Flies, Prof. T. D. A. Cockerell, 693
Discharge Tube Phenomena, Some New, Prof. R. Whiddington, 114
Discovery and Invention, 905
Discovery : Committee, appointment of F. D. Ommaney, F. J. Hart, and A. H. Laurie on the scientific staff of the, 495 ; Equipment, etc., of the, 105 ; Investigations, Progress of the, Dr. S. Kemp, 483 ; Plans for the Voyage of the, 663 ; *II.*, The, 798, 956 ; The Scientific Staff of the, 348
Disease in South America, Archæology of, Prof. R. L. Moodie, 666
Distribution Coefficients, An Extension of the Conception of the, I. W. Wark, 395
Dog Distemper and Immunisation, P. P. Laidlaw, 991
Dolphin, White-sided, in Scottish Waters, 999
Doryanthes excelsa, Life-history of (2), I. V. Newman, 639
Do. X Flying Ship, Flight of the, 701
Dragonflies in Folk-Lore, Dr. W. M. Davies ; Dr. W. T. M. Forbes, 55
Draper Catalogue, The Systematic Errors of the, A. Bemporad and L. Genovese, 167
Drosophila melanogaster : Age Changes in Alcohol Tolerance in, Prof. R. Pearl, Florence Barclay White, and J. R. Miner, 395 ; A Homozygous Translocation, T. Dobzhansky, 675 ; Growth of Larvæ of, Influence of Thyroid Gland Feeding on the Acceleration of the, W. W. Alpatov, 603
Druckschieferung im varistischen Gebirgskörper, Über, Prof. A. Born, 686
Durham, University of, Philosophical Society, election of officers, 853
Dutch East Indies : Climate of the, 634 ; Newer Tertiary Fossils from the, F. Siemon, 962

Dwarf, a New Mendelian Recessive Character of the House Mouse, G. D. Snell, 898
Dynamical : System, The Brachistochronic Motion of a, A. J. McConnell, 251 ; Systems, Prof. G. D. Birkhoff, 612

Early Man in East Africa, 413
Earth : Flexures : their Geometry and their Representation and Analysis in Geological Section, with special reference to the Problem of Oil Finding, 644 ; Old Mother, Prof. K. F. Mather, 873 ; Rotation of the, and Magnetostriction, A. H. R. Goldie, 303 ; -shine, Measures of the Brightness of, Prof. H. N. Russell, 106 ; The, and its History : a Textbook of Geology, Prof. J. H. Bradley, Jr., 836 ; its Origin, History, and Physical Constitution, Dr. H. Jeffreys. Second edition, 296 ; -Tilting by Tidal Loading, R. Takahasi, 633
Earth's : Crust, The Thermal Instability of the, Dr. J. H. J. Poole, 1006 ; Rotation, Relativistic Questions on the Proofs of the, G. Giorgi and A. Cabras, 79
Earthquake : in New Zealand on June 17, 385, 457 ; recorded at Kew, 31, 68, 208, 316 ; Sounds heard at Great Distances, A. Thomson, 687 ; Dr. F. J. W. Whipple, 688 ; south of Newfoundland, The, and Submarine Canyons, Prof. J. W. Gregory, 945 ; The Chilean, of 1922, Dr. C. Davison, 391
Earthquakes, Annual Periodicity of, Dr. C. Davison, 71
Earthworm Fauna of Illinois, Changes in the, F. Smith, 245
Earthworms : Giant, of South Gippsland, C. Barrett, 387 ; The Ganglion Cells of, F. Ogawa, 318
East : Africa, Early Man in, 413 ; African Archæology, L. S. B. Leakey and J. D. Solomon, 9
Echinococcus in New South Wales, I. C. Ross, 70
Echinoderms and Teleostei, Northern, Dr. T. Mortensen and I. Lieberkind, 561
Echinoidea, A Monograph of the. 1 : Cidaroidea, Dr. T. Mortensen, 329
Echinus esculentus, Regeneration of Spines in, H. C. Chadwick, 760
Echo Signals, Long retarded, P. O. Pedersen, 42
Economic Entomology, Dr. L. Eastham, 327
Ectocarpus, Reproduction and Sex in, Miss Margery Knight, 425
Edinburgh University : Conferment of degrees, C. B. Williams appointed Steven lecturer in agricultural and forest zoology, 112 ; award of the Cameron prize to Sir Leonard Rogers, 164 ; Dr. T. W. M. Cameron appointed lecturer in helminthology : A. L. Bennett appointed lecturer in zoology, 213 ; gifts to, by T. B. Macaulay, 743 ; Dr. C. H. O'Donoghue appointed reader in zoology, 895
Education : Aspects of Psychology in, Dr. C. W. Kimmins, 516 ; in Kent, 1923–1928, E. Salter Davies, 284 ; in other Countries, Major Trends of, 323 ; Matter and Method in, Mary Sturt and Ellen C. Oakden, 545 ; Modern Movements in, Dr. C. W. Kimmins, 150 ; Vocational, Objectives and Problems of, edited by Prof. E. A. Lee, 545
Egg : -albumen, The Dielectric Polarisation of Solutions of, Mlle. Y. Garreau and N. Marinesco, 466 ; White and Egg Yolk, Hydrogen Ion Concentration of, Changes with Age of the, J. C. Baird and J. H. Prentice, 969
Egyptian Medicine, W. R. Dawson, 776
Einstein's New Theory, A. Palatini, 115
Elasmobranch Fishes, The, Prof. J. F. Daniel, 440
Electric : Arc, Motion of an, in a Magnetic Field under Low Gas Pressure, R. Tanberg, 371 ; Charge on Rain, The, Thora C. Marwick, 861 ; Charges developed in certain Amorphous Dielectrics under the Action of Pressure, The, A. Turpain and M. Durepaire, 933 ; Express Trains, The Speeding-up of, 996 ; Furnaces : for Non-ferrous Metals, Progress in, M. Tama, 466 ; Small, List of, A. Gallenkamp and Co., Ltd., 736 ; Generation Companies of France, The interlinked Group of, 958 ; Lamps, Rating, 211 ; Power in Quarries, 35 ; Supply, Storage Plant for, A. G. Christie, 383 ; Traction, The Proposed Conversion of the Brighton Line from Steam to, A. T. Dover, 735 ; Transmission Cables, Overhead, Effect of Temperatures attained in, A. V. Zeerleder and P. Bourgeois, 466 ; Trolley Vehicles, Bradford Corporation and, 552
Electrical : Communications, Sir Thomas Purves, 702 ; Installation Work, 958 ; Power, Limits of Economical Transmission of, Prof. E. W. Marchant, 275 ; Resistance in Metals, Sir Oliver Lodge, 634
d'Électricité industrielle à l'usage des élèves-ingénieurs, Cours, leçons professées à l'Institut industriel du Nord, A. Defretin. Tome 1 : L'Électricité dans la science de l'ingénieur, 685
Electricity : in the Bedford area, 242 ; in the Gaseous Discharge, Latent Carriers of, S. A. Ratner, 288 ; Some Applications of Adiabatic Invariants to, D. Graffi, 359 ; Supply : in Great Britain, The, Sir Philip Dawson, 629 ; of the North-east of England, The Scheme for the, 315
Electrification : in Russia, Dr. Segal, 997 ; of British Railways, The : Sir Philip Dawson, 456 ; Appointment of a committee on the, 422
Electrified Omnibuses, On Prof. Boys's Letter concerning, C. Macnamara ; W. W. Davidson, 276
Electrodynamic Theory, Classical, 367
Electrolysis of Water with Alternating Current, A. Canaud, 41
Electrolytes, Resistance of, to High Frequency Oscillating Currents, R. Šimůnek, 897
Electromagnetic Waves, Penetration of Rocks by, Prof. A. S. Eve, Dr. D. A. Keys, and F. W. Lee, 178
Electrometers, The Sensitiveness of, E. Perucca, 862
Electron : Collisions with Molecules and Resultant Quantum Losses, Prof. R. Whiddington, 758 ; Properties of the, R. D. Kleeman, 728 ; Scattering in Gases, The Theory of, A. C. G. Mitchell, 467 ; The Charge of an, Prof. A. S. Eddington, 840 ; Waves, Drs. Davisson and Germer, 34
Electronic Emission in a Vacuum Tube (2), L. Tieri and V. Ricca, 359
Electrons : An Optical Law for, E. Rupp, 108 ; and Ions, Recombination of, Prof. R. Seeliger, 280 ; Capture of, by α-Particles, Prof. B. Davis and A. H. Barnes, 389 ; from Cold Metals, Emission of, T. E. Stern, B. S. Gosling, and R. H. Fowler, 40 ; Low-speed, The Photographic Action of, B. Rossi and G. Bernardini, 970 ; Low Velocity, Action of, on Micro-organisms, Dr. D. A. Wells, 983 ; Scattering of : N. F. Mott, 72 ; by Gold, N. F. Mott, 986 ; that are 'pulled out' from Metals, E. H. Hall, 216
Electrostatic Moments of Molecules, On the Direct Determination of the, R. J. Clark, 40
Elektrizität und Eiweisse, insbesondere des Zellplasmas, Dr. H. Pfeiffer, 609
Elektrodynamik, Lehrbuch der, Prof. J. Frenkel. Band 2 : Makroskopische Elektrodynamik der materiellen Körper, 367
Elements for the Universe, The possible, R. C. Tolman, 288
Elk in Sweden, Increase of, 999
Elliptical Polarisation produced by Reflection at the Surface of Solutions of Fatty Acids in Water, The, C. Bouhet, 252
'El Tunel del Estrecho de Gibraltar', D. R. de Buen, 771
Emanation Therapy, Physical Basis of, Prof. S. Meyer, 927
d'Embryologie, Traité, comparée des invertébrés, Prof. C. Dawydoff, 332
Emission Centres, The Charge of, as shown by the Polarity of the Electrodes, A. Occhialini, 115
Emotion and Delinquency : a Clinical Study of Five Hundred Criminals in the Making, Dr. L. Grimberg, 545
Empire : Agriculture and the, Sir Robert B. Greig, 304 ; Development Board, A proposed, Sir Robert Hadfield, Bart., 549 ; Meteorologists, Conference of, 427
Enantiomers, The Physical Identity of, Dr. A. N. Campbell, 792
Enantiomorphism in Organic Compounds, Prof. J. Read, I. G. M. Campbell, and T. V. Barker, 1001
'Encyclopædia Britannica', The, Dr. H. A. Baylis, 987
Endoskeleton, True, in Insects, S. Maulik, 668

Energy : Sir Oliver Lodge, 87 ; and Heat, 473
Engineering : Economics, T. H. Burnham, 538 ; Science and, Prof. F. C. Lea, 196, 415 ; H. P. Vowles, 618 ; The Profession of, Essays, edited by D. C. Jackson, Jr., and Prof. W. P. Jones, 684
English : Gypsy Taboos, T. W. Thompson, 460 ; Vocabulary, Technical, E. W. Ashcroft, 492 ; Walnut Trees in Victoria, A Crown Rot of, Isabel C. Cookson, 43
Entomology : Applied, The Problems of, Prof. R. A. Wardle, 327 ; Economic, Dr. L. Eastham, 327 ; Systematic, The Principles of, Prof. G. F. Ferris, 721
Enzyme : Research, Prof. A. R. Ling, 404 ; Untersuchungen über, Prof. R. Willstätter. Bände 1 u. 2, 867
Enzymes, Prof. A. R. Ling, 867
Eocene : Crab, New, from Florida, Miss Mary J. Rathbun, 461 ; Tropical Forest in the Peruvian Desert, An, E. W. Berry, 288
Epidemic Diseases, 435
Epidemicity, The Nature of, 221
Epidemics, The Genesis of, and the Natural History of Disease : an Introduction to the Science of Epidemiology based upon the study of Epidemics of Malaria, Influenza, and Plague, Lieut.-Col. C. A. Gill, 221
Epidemiology, Old and New, Sir William Hamer, 435
Equilibrium $CO_2+C=2CO$, The, Prof. J. W. Cobb and F. E. Dent, 775
Erdoberfläche, Rhythmische Phänomene der, H. Kaufmann, 722
Eriosomea, Anolocyclic Elm Aphids, etc., A. Mordvilko, 324
Eros, Comparison Stars for, Catalogue of the, Prof. P. Stroobant, 69
Eruptive and Crystallophyllian Rocks of Brittany, The Heavy Minerals of the, L. Berthois, 77
Ester Synthesis, New, H. Lux, 462
Ether : Protest against the Monopoly of the, Dr. J. Robinson, 593 ; The Electronic Theory of the, and of Light, A. Véronnet, 41
Etherate of Magnesium Bromide, The Retrogradation of the C_6 Ring into the C_5 Ring with the Aid of the, P. Bedos, 431
Ethylene : Oxides in the Terpene Series, Transpositions of, M. Faidutti, 1007 ; The Polymerisation of, by the Silent Discharge, G. Mignonac and R. Vanier de Saint-Aunay, 286
Eucalyptus dives, Occurrence of a Number of Varieties of, as determined by Chemical Analysis of the essential Oils (pt. 3), A. R. Penfield and F. R. Morrison, 639
Eugenics ? What is, Major L. Darwin, 686
Euryale, Leaf Growth in the Giant, Y. Okada, 497
Eutectics and Igneous Rocks, Prof. W. Wahl, 280
Evaporating : Plant, A Novel, 857 ; Condensing and Cooling Apparatus : Explanation Formulæ and Tables for use in Practice, E. Hausbrand. Translated by A. C. Wright. Fourth English edition, revised and enlarged by B. Heastie, 573
Everest, Mount, Height of, 108
Evolution : by Symbiosis, H. Reinheimer, 909 ; Continuous or Discontinuous ? Dr. F. B. Sumner, 245
Examinations, Reports on, 393
Exercitatio Anatomica de Motu Cordis et Sanguinis in Animalibus, Dr. William Harvey. With an English translation and annotations by Prof. C. D. Leake, 722
Experimentalphysik, Handbuch der, Herausgegeben von W. Wren und F. Harms : unter Mitarbeit von H. Lenz, Band 13, Teil 1, 297 ; Band 7, Teile 1 und 2, 475 ; Band 8, Teil 1. Bearbeitet von Prof. A. Eucken, 473 ; Band 9, Teil 1 : Hohe und tiefe Temperaturen, von Prof. H. von Wartenberg ; Gasverflüssigung und ihre thermodynamischen Grundlagen, von H. Lenz ; Wärmeleitung, von Prof. O. Knoblauch und H. Reiher ; Wärmestrahlung, von W. Wien und Dr. C. Müller, 541 ; Band 20, Teil 1 : Physiologische Optik, Dr. A. König, 751
Explosions of Heating Apparatus, 886

Factories, H.M. Chief Inspector of, Report for 1928, 383
Faraday Centenary Celebrations, Arrangements for the, 275
Farming, Scientific, in Germany, 569
Faroes, Marine Hydrozoa of the, Dr. P. L. Kramp, 1000
Fatigue Testing Machine, H. S. Rowell, 320
Fatty : Acids, Influence of, on the Maximum of Current due to Atmospheric Oxygen in Electrolysis, J. Rasch, 897 ; Oils, The Grouping of, with Special Reference to Olive Oil, E. R. Bolton and K. A. Williams, 780
Fauna, Torrential, Ecology, Bionomics, and Evolution of the, Dr. S. L. Hora, 780
Faune de France. 20 : Coléoptères ; Cerambycidæ, Prof. F. Picard, 613
Fechner's Law in Colour Sensation, The General Applicability of, Prof. W. Peddie, 791
Feelings and Emotions : the Wittenberg Symposium, A. Adler, and others, 8
Fermentation, Action of Sea Water in extremely small amounts on, C. Richet and M. Faguet, 431
Fermente, Die Methodik der, Herausgegeben von C. Oppenheimer und L. Pincussen. Lief. 4 und 5, 404
Ferrocobalts, The Magnetisation to Saturation of, etc., P. Weiss and R. Forrer, 896
Ferro-cyanomolybdates and Analogous Compounds of Ruthenium and Osmium, G. A. Barbieri, 638
Ferrous Compounds and Nitric Oxide, Reactions between L. Cambi and A. Clerici, 79
Fersmanite, a New Mineral from the Khibin Tundras, A. N. Labunčov, 394
Fertilisers and Manures, Sir A. Daniel Hall. Third edition, 530
Fertility Figures, Miss M. A. Murray, 352
Field : and Colliery Surveying : a Textbook for Students of Mining and Civil Engineering Surveying, T. A. O'Donahue and T. G. Bocking. New edition, 123 ; Museum and the Child, 349 ; Annual Report for 1928, 551
Fight against Disease : Summer No., 385 ; Autumn No., 925
Fijian Game in Assam, A, J. H. Hutton, 554
Filipinos, Cranial Capacity of, Dr. J. C. Nañagas, 424
Films, Educational, Appointment of a Committee on, 923
' Fine Structure ' Constant, The, Prof. A. Sommerfeld, 319
Finland, Annual Forest Report for, 1927, 924
Fireball, Brilliant Detonating, on July 28, 244
Fireballs, Recent, W. F. Denning, 926
Firedamp, Ignition of, M. J. Burgess and Prof. R. V. Wheeler, 598 ; Prof. R. V. Wheeler and Dr. H. F. Coward, 556
Fischer : Mrs., or the Future of Humour, R. Graves, 685
Fish in Water, Resistance to the Progress of, A. Magnan and A. Sainte-Laguë, 969
Fisheries : Industry in Japan, S. Kato, 927 ; Investigations, International, 322
Fishery Research on the North Sea and Baltic, W. Schnakenbeck, 886
Fishes : Cutaneous Sense Organs in, D. Miyadi, 632 ; from Ontong Java, Melanesia, G. P. Whitley, 324
Fitness for Work, Prof. T. H. Pear, 176
Flame : Speeds, W. Payman and Prof. R. V. Wheeler, 426 ; The Movements of, in Carbonic Oxide-Oxygen Explosions, Prof. H. B. Dixon, 580
Flavelle Medal of the Royal Society of Canada, presentation of the, to Prof. A. H. R. Buller, 110
Flavindo-genides, Preparation and Oxidation of, Prof. H. Ryan and G. Cruess-Callaghan, 251
Flies : The Type Locality of certain, Described by Macquart in " Diptères exotiques, Suppt. 4 ", G. H. Hardy, 324 ; Typical, a Photographic Atlas of Diptera, E. K. Pearce. Series 3, 124
Flight, The Science of : Aeroplanes, Seaplanes, and Aero Engines, Capt. P. H. Sumner, 8
Floridan Tree Snails, C. T. Simpson, 424
Flowering Plants of the Northern and Central Sudan, Grace M. Crowfoot, 533
Flowers of the World, 611
Fluid Flow in Pipes and Channels, S. J. Davies and C. M. White, 281
Fluorescence : The Quantum Theory of, E. Segré, 359 ; Phenomena, Peculiar, in the Shells of Gastropods (Families Trochidæ and Turbinidæ), E. Furreg and F. Querner, 287
Folding ? Competent or Incompetent, C. E. Dobbin, H. W. Hoots, C. H. Dane, and E. T. Hancock, 461
Foliation in its relation to Folding in the Mona Complex at Rhoscolyn (Anglesey), E. Greenly, 1006

Folk-Lore: Natural History and, C. Oldham; L. Rowland, 229; Museum for England, A, 289
Food: Investigation Board, Report for 1928, 822; Index to the Literature of, Agnes Elisabeth Glennie, 629; The Storage of, 822
Foraminifera: their Classification and Economic Use, Dr. J. A. Cushman, 680
Force which tends to Displace the Continents towards the West, Magnitude of a, R. Berner, 394
Forecasting, Long Period, E. T. Quayle, 109
Forefathers, Our, the Gothonic Nations, Dr. G. Schütte, 531
Forest: Nursery, Control of Diseases and Weeds in a, A. E. Muskett, 481; Products Research Laboratory, Princes' Risborough, Grant to the, by the Empire Marketing Board, 349
Forestry: Conference, The Third British, 1928, 321; in Kenya Colony, 893; Question in Great Britain, The, Prof. E. P. Stebbing, 476; Research in India, 778; The Writer of the Article, 840
Forests: and Rainfall, J. W. Nicholson, 820; of the Andaman Islands, The, A. Rodger, 249
Form in Physics and Biology, The Problem of, N. Rashevsky, 10
Forthcoming Books of Science, 546
Fortpflanzung und Befruchtung als Grundlage der Vererbung, M. Hartmann, 262
Fossil: Insects of the South Wales Coalfield, H. Bolton, 861; Marsupial, A Rare, H. A. Longman, 555; Plants and Mountain Uplift in the Pacific States, E. W. Berry, 467; Vertebrates of North America, Dr. O. P. Hay, 928; Wood from Central Australia, A, A. B. Walkom, 287
Fossils, Preservation of, E. G. Radley, 388
Foucault Pendulum, to be re-suspended in the Science Museum, 241
Fourmis, Histoire des, M. de Réaumur. Avec notes de Prof. C. Pérez, 613
Fraunhofer Lines, Faint, A possible Origin of, Daulat Singh Kothari, 90
French, The British and, Associations at Havre, 355
Frenkel Adsorption Isotherm, The, F. J. Wilkins and A. F. H. Ward, 482
Fresh-water: Algæ of Africa, The (8), Prof. F. E. Fritsch and Florence Rich, 78; Fauna of the Malay Peninsula, C. Dover, 499; Mussels of the District of Columbia, Anatomy of, Lucy Reardon, 318; Plankton, Experimental Research on, Dr. E. Naumann, 961
Froghopper Problem in Trinidad, The, Dr. A. D. Imms, 558
Frost Heaving, S. Taber, 388
Fuel: Problems, Physics in, Dr. C. H. Lander, 894; Research, Prof. J. W. Cobb; Dr. C. H. Lander, 858; Board, Report of the, for the Year ended March 31, 1929, 858
Fulminating Material, Study of, E. Mathias, 41, 781
Fülöppite, a New Hungarian Mineral of the Plagionite-semseyite Group, I. de Finály and S. Koch, 76
Fumariaceæ, The Tubular Cells of, R. Kloimwieder, 971
Fungi: an Introduction to Mycology, J. Ramsbottom, 403; Comparative Morphology of, Prof. E. A. Gaumann. Translated and revised by Prof. C. W. Dodge, 403; found in Milk, H. A. Cummins, Violet E. C. Kennelly, and M. Grimes, 285; Studies of, 403
Fur Dermatitis, Chemical Tests in relation to, H. E. Cox, 602
Furnace Walls, Water-cooled, Babcock and Wilcox, 320
Furunculosis and other Infectious Diseases among Salmon, Trout, etc., appointment of a Committee upon, 350

Galactic Co-ordinates, Conversion Tables for, Prof. F. Emanuelli, 930
Gale in England, A Severe, 922
Galilei, Galileo, Memorials of, 1564–1642, J. J. Fahie, 869
Galileo, Memorials of, Mrs. Dorothea Waley Singer, 869
Gallium, The Quantitative Analysis of (3), A. Brukl, 745
Gall-making Coccids and Descriptions of New Species, W. W. Froggatt, 639
γ-anisylidene-methyl-ethylketone, Some Derivatives of, Prof. H. Ryan, P. McGeown and J. Keane, 251
Gannets, A Census of, Dr. J. Ritchie, 496
Garnet-bearing Dyke, A, near Moruya, N.S.W., Ida A. Brown, 395
Garo Ethnology, Dr. B. Bonnerjea, 352
Gas: Analysis, A Nomogram for use in, J. H. Coste, 602; Discharges, Spiral Forms in, Drs. S. P. McCallum and W. T. Perry, 984; Natural, J. Kewley, 775
Gaseous: Combustion at High Pressure (13), D. M. Newitt, 40; Ions, Recombination of, Profs. Loeb and Marshall, 634; Stellar Structures, Stability of, B. P. Gerasimovič, 288
Gases: Adsorption of, Prof. K. F. Herzfeld, 821; Incoherent Scattering in, Further Investigation on, F. Rasetti, 93; in Liquids, The Diffusion and Transition of, H. Mache (1), 782; Specific Heats of, A Flow Method for comparing the, P. M. S. Blackett, P. S. H. Henry, and Dr. E. K. Rideal, 825; The Thermodynamics of, which show Degeneracy, G. N. Lewis and J. E. Mayer, 216
Gasteromycetes of the Eastern United States and Canada, The, Prof. W. C. Coker and Prof. J. N. Couch, 403
Gelatin, Nitrogen Distribution of, 462
Gelatine Solutions, The Magnetisation Coefficient and Structure of, M. Fallot, 77
Genetical Studies at Cold Spring Harbor, Dr. J. Belling, 461
Genetics: Bibliography of, H. Matsuura, 890; International, 295; The Species Problem in the Light of, J. B. S. Haldane, 514
Geneva, Canton of, Presence of Old Glacial and Interglacial Formations in the Northern Part of the, A. Yayet, 78
Geochemistry, Problems of, 1
Geography, An Introduction to, Prof. H. J. Fleure, 982
Geological: Society of London, election of foreign members, 31; Survey of Great Britain, Summary of Progress for 1927, 248; Surveys: and Development, Sir Albert E. Kitson, 374; The Utility of, to Colonies and Protectorates of the British Empire, Sir Albert Kitson, 195
Geologie, regionalen, Handbuch der, Herausgegeben von Prof. G. Steinmann und Prof. O. Wilckens. Band 7, Abt. 7a: The Union of South Africa, A. W. Rogers, and others, 89
Geology in Great Britain, 248
Geometrical Optics, The Teaching of, 66
Geophysics: Elements of, as applied to Explorations for Minerals, Oil, and Gas, Dr. R. Ambronn. Translated by Dr. Margaret C. Cobb, 52
Germanium Dioxide in Aqueous Solution; Germanic Acid, W. Pugh, 394
Germany, Scientific Farming in, 569
Giant: Aeroplanes and their Design, Dornier, 100; Panda, Trailing the, T. Roosevelt and K. Roosevelt, 944
Gibbs, J. Willard, The Collected Works of. 2 vols., 119
Gifford Lectures, The, 1927 and 1928, Dr. J. S. Haldane, 259
Glaciation of Clun Forest, etc., The, Dr. A. R. Dwerryhouse and A. A. Miller, 861
Glare, W. S. Stiles, 818
Glasgow University: impending retirement of Sir Donald Macalister, 250, 272; Sir Donald Macalister elected Chancellor; Prof. R. S. Rait appointed Principal, 743; E. B. Bailey appointed professor of geology, 968
Glass: Annealed, The Structure of, P. P. Lazarev and S. Lioznianskaia, 167; Technology, Society of, Formation of a London Section of the, V. Stott elected honorary secretary, 664
Glasses Transparent to Ultra-violet Radiation, A. R. Wood and M. N. Leathwood, 441
Glossopteris Flora, Early, Botanical Records of the Rocks: with special reference to the, Prof. A. C. Seward, 449
Gmelins Handbuch der anorganischen Chemie. Achte Auflage: System-Nummer 21: Natrium; System-Nummer 31: Radium und Isotope, 534
Gold: Geology of (South Africa, Australia, New Zealand), E. J. Dunn; Dr. F. H. Hatch, 835; Stability of the Value of, 670; The Crystallisation of, from the Liquid State, C. O. Bannister, 430; The Problem of the Future Value of, D. T. Jack, 670
Golgi Body and Vacuoma, Prof. D. R. Bhattacharya and, Dr. R. S. Das, 692

Gorgas Memorial : Institute of Tropical and Preventive Medicine, The, 350 ; Laboratory of Tropical Disease, The, 518
Gorgonacea from Panama, Prof. S. J. Hickson, 738
Government Chemist, Work of the, 670
Graf Zeppelin, 'Round-the-World' Flight of the, 384
Gramophone Records, Scientific Uses of, Dr. W. H. George, 741
Granada, Afforestation and Stabilisation in, J. M. G. Nájera, 962
Graptolite Centenary : 1829–1929, Dr. H. M. Ami, 766 ; Prof. W. W. Watts, 877
Graptolites from the Federal Territory, W. J. Harris and R. A. Keble, 167
Grass : in Orchards, 529 ; Orchard, The English, and the Principles of Fruit Growing, A. H. Hoare, 529 ; Seeds, Vitamin Contents of, from treated Plots, Dr. M. I. Rowlands, 760
Gravimetric Observations made in : 1927–1928 in the Emba area, B. Numerov and B. Kozlovskij, 897 ; 1928 near Lake Baskuntchak, B. Numerov and N. Samsonov, 897
Gravitation Waves in the Atmosphere, F. M. Exner, 287
Great Barrier Reef : Expedition, Final Report on the, Dr. C. M. Yonge, 694 ; J. A. Steers, 706
Greek Thought and the Origins of the Scientific Spirit, Prof. L. Robin. Translated by M. R. Dobie, 612
Green Bed Group of the Scottish Dalradian, some Mineralogical and Chemical Changes induced by Progressive Metamorphism in the, F. C. Phillips, 896
Greenland, Expedition to Ice-sheet of, 31
Greenwich Observations, 1927, 704
'Grid' System, The, and the Farmer, R. E. Turnbull, 242
Growth : Gradients and the Axial Relations of the Animal Body, M. Perkins, 299 ; Rate is controlled by an Autocatalytic Process, An Inherent Defect in the Theory that, G. D. Snell, 216
Guinea-pigs, Functional Disturbances of Hearing in, after long exposure to an Intense Tone, M. Upton, 216
Gulf Stream, The, H. A. Marmer, 597
Gum Arabic, Composition of, 109

Hæmin, Synthesis of, H. Fischer, 462
Haldane Memorial Lecture, The, Lord Justice Sankey, 931
Hall Coefficient, the Thermo-electric Power, and the Resistance in Ordinary and Compressed Bismuth, A Comparison between the Variations with the, R. Fedele, 862
Halogenides in presence of Sulphites, Determination of, O. Tomíček and A. Jánský, 898
Halosphæra in the North Sea, C. H. Ostenfeld, 460
Hanbury Memorial Medal, Presentation of the, to Prof. H. H. Rusby, 593
Hautes Montagnes, Contribution à l'étude du peuplement des P. Allorge, and others, 532
Hawaiian Non-Marine Mollusca, E. L. Caum, 70
Hay Rations for Dairy Cows, R. Bontflour, 999
Hayti, The Spirit Cult in, Dr. Elsie Clews Parsons, 107
h, c, and e^2, Relationship between, Dr. W. N. Bond, 408
He_2 Rotation Terms, Properties of the, Prof. W. E. Curtis and A. Harvey, 12
Health, Ministry of, Annual Report of the, 350
Heat : Engines, 834 ; Insulators, Dr. E. Griffiths, 707 ; Intermediate, Dr. R. A. Houstoun, 87 ; Light, and Sound, P. J. Lancelot Smith, 87 ; Resistance Curve, The, C. Dukes, 780 ; Storms, The Genesis of, and their Prediction, J. Lugeon, 503
Heating : and Electric Furnaces, O. Dony, 934 ; Systems, Profs. Willard, Kratz, and Day, 247
Heaviside's Operational Method, D. P. Dalzell, 933
Heisenberg's Indetermination Principle and the Quantum, Prof. G. E. M. Jauncey, 57
Helium : Band Lines, Fine Structure in the, Dr. G. S. Monk and Prof. R. S. Mulliken, 91 ; -rich Natural Gas, Origin of, R. C. Wells, 774
Hellenic : Society, The, 1879–1929, 121 ; Studies, The Journal of. Vol. 49, Part 1, 121
Helminthology : A Manual of, Medical and Veterinary, Dr. H. A. Baylis, 261
1 : 6-Heptadiine and 1 : 8-Nonadiine, Lespieau and Journaud, 42
Heraclitus : or the Future of the Films, E. Betts, 649
Heriot-Watt College, Calendar of the, 779
Herring Research at Cullercoats, Prof. A. Meek, 159
Heterodyne Null Method of Measuring Dielectric Constant, The, Prof. P. N. Ghosh and P. C. Mahanti, 13
Heterogenic Growth in the Appendages of Crustacea, J. T. Cunningham, 14
$HgBr_2 . 2NH_3$ and $HgCl_2 . 2NH_3$, Dissociation of the Compounds, M. François, 826
Hibernia : or the Future of Ireland, B. C. Waller, 685
High : Frequency : Currents, An Absolute Method of Measuring, Dr. R. L. Smith-Rose, 651 ; Discharge in Organic Vapours, Prof. P. N. Ghosh and B. D. Chatterjee, 654 ; Striations in, K. A. MacKinnon and Prof. J. K. Robertson, 55 ; -pressure Carbon Bands, Structure of the, and the Swan System, Dr. R. C. Johnson and R. K. Asundi, 40 ; -speed Races, Methods of Timing, C. C. Mason, 338
Himalayan Journal, No. 1, 67
d'Histologie, Éléments, Prof. P. Bouin, Tome 1 : Cellule, 88
Historical Scientific Apparatus, Exhibition of, 816
Homogeneous Catalysis : N. A. Milas, 603 ; A General Discussion on, 537
Hop Drying, Experimental, A. H. Burgess, 34
Hoplosebastes armatus, a New Genus and New Species of the Family Scorpænidæ from Japan, P. Schmidt, 324
Hops, New Varieties of, Prof. E. S. Salmon, 1000
Horse Serum, Analysis of, Influence of the Ionic Concentration of the Medium on the Activity of the, Brocq-Rousseu, Mme. Z. Gruzewska, and G. Roussel, 826
H-rays of Different Range, The relative Brightness of Scintillations of, E. Kara-Michailova and B. Karlik, 827
Hudson River, The Suspension Bridge over the, E. W. Stearns, 886
Human : Skull, Evolution of the, Prof. W. K. Gregory, 596 ; Motivation, The Fundamentals of, Prof. L. T. Troland, 544
Humulus, Nature of the Sex Chromosomes in, O. Winge, 42
Hunter Valley between Greta and Muswellbrook, The Structural and Tectonic Geology of the, H. G. Raggatt, 467
Hurricanes, Buildings to withstand, R. Fleming, 281
Huxley Memorial : Medal of the Royal Anthropological Institute, awarded to Prof. A. H. Sayce, 65 ; presented to Baron Erland Nordenskiöld, 850 ; Lecture of the Royal Anthropological Institute, The, Baron Erland Nordenskiöld, 850
Huygens Lenses, Three, Prof. R. A. Sampson and Prof. A. E. Conrady, 251, 595
Hydatids in South Australia, Dr. I. C. Ross, 279
Hydraulic Pneumatic Engineering, J. O. Boving, 1001
Hydrocarbons : Gaseous Unsaturated, Ozonation of the, E. Briner, P. Schnorf, and R. Meyer, 43 ; The Direct Oxidation of, by the Air, Dumanois and Mondain-Monval, 934 ; Varieties of the Temperature of Spontaneous Inflammation of, in Admixture with various Substances, A. Grebel, 1007
Hydrogen : and Nitrogen, Specific Heats of, The Temperature Variation of the, J. H. Brinkworth, 825 ; and the Many Lined Spectrum, A New Connection between the Absorption Spectrum of, Prof. O. W. Richardson, 408 ; Atom, in the Electric Field Asymmetry in the Radiation from the, Prof. J. Stark, 125 ; The continuous Spectrum of the, D. Chalonge and Ny Tsi Zé, 431 ; Catalyst, The Selective Action of a, M. Bourguel and Mlle. V. Gredy, 934 ; Ion Concentration, Petal-colour and, Buxton and Darbishire, 319 ; in Geissler Tubes, The Disappearance of, R. Delaplace, 1007 ; Liquid, Existence in, of two distinct kinds of Molecules, Prof. J. C. McLennan and J. H. McLeod, 491 ; Molecule, The, Prof. O. W. Richardson and Dr. P. M. Davidson, 597 ; The Critical Potentials and Low Tension Arcs in, S. Vencov, 252
Hydrolytic Adsorption at Colloid Surfaces, S. W. Pennycuick, 987
Hydroquinone, The Autoxidation of R. Dubrisay and A., Saint-Maxen, 896

Hydrostatics, Experimental, and Mechanics for School Certificate Students, E. Nightingale, 332
Hydrozoa, Northern, Dr. H. Broch, 387
Hygiene and Tropical Medicine, The London School of, 162
Hymenomycetes Fungi, The Soluble Ferments Secreted by the, L. Lutz, 252

Ice : Crystal Structure of, Dr. W. H. Barnes, 857 ; -berg Detection, Prof. H. T. Barnes, 337 ; -bergs in a High Latitude, R. W. Gray, 479 ; on the North Coast of Norway, The Abnormal Arrival of, C. Rabot, 115 ; Engineering, Prof. H. T. Barnes, 89
Iceland, The Botany of, edited by Dr. L. Kolderup Rosenvinge and Dr. E. Warming. Vol. 2, Part 2 (7, 8), 534
Idiomorphic Crystals of Cuprous Oxide in Copper, C. Blazey, 466
Igneous Rocks : Orbicular Structures in, F. Loewinson-Lessing and O. Vorobjeva, 781 ; The Evolution of the, N. L. Bowen, 474
Illumination : International Commission on, Report of the, 925 ; Progress in, 663
Imperial : Bureau of Soil Science, appointment to the, of A. J. Lloyd Lawrence and Miss H. Sherbatoff, 105 ; College of Science and Technology : H. T. Tizard appointed rector of the, 105 ; Report of the Technical Optics Committee, 968 ; Mycology, 729
Incandescent Electric Lamp, Celebration of the 50th Anniversary of Edison's, 700
Index Kewensis Plantarum Phanerogamarum. Supplementum septimum nomina et synonyma omnium generum et specierum ab initio anni MDCCCCXXI usque ad finem anni MDCCCCXXV nonnulla etiam antea edita complectens. Ductu et consilio A. W. Hill, 832
India : Cold Wave in, February 1929, Probable Origin of the, Dr. S. C. Roy and G. Chatterji, 579 ; Early Man in, Col. S. Sewell and Dr. B. S. Guna, 961 ; Education in, Progress of, 1922–27, R. Littlehailes, 779 ; Forestry Research in : 778 ; The Writer of the Article, 840 ; Meteorology in, Dr. C. W. B. Normand ; The Writer of the Article, 335 ; The Mineral Production of, F. L. G. Simpson, 925
Indian Oligochæta, K. S. P. Aiyer, 424
Indium, The Determination of, and its Separation from the Monoxides and Sesqui-oxides, L. Moser and F. Siegmann, 1007
Indus Flood, The, 421
Industrial : and other Wastes, The Recovery and Use of, J. B. C. Kershaw, 755 ; Maladies, Thirty Years' Experience of, Sir Thomas Legge, 494 ; Waste and its Treatment, 755
Industry : Modern, Craftsmanship in, 253 ; Science and, 361
Infinite Series, Theory and Application of, Prof. K. Knopp. Translated by Miss R. C. Young, 943
Infra-red : Absorption in Organic Compounds, Fine Structure of, and the Raman Effect, Dr. R. B. Barnes, 300 ; Spectra, 789 ; C. P. Snow and A. M. Taylor, and others, 72 ; Vibrations of Simple Crystals, Effect of Volume Changes on the, E. O. Salant, 467
Infrarouge, Le spectre, Dr. J. Lecomte, 751
Inorganic Quantitative Analysis, Prof. H. A. Fales, 262
Inosite, Inactive, The Configuration of, S. and T. Posternak, 78
Insects : Destructive and Useful, their Habits and Control, Prof. C. L. Metcalf and W. P. Flint, 327
Institut International de Bibliographie, Annual Conference of the, 559
Insulating Liquids, so-called, Existence of a Conducting State of, L. Brüninghaus, 41
Intelligence, Testing, and Achievement, Dr. A. J. Levine and L. Marks, 545
Intensive Drying on Chemical Changes, Effect of, Prof. H. B. Baker and Prof. W. A. Bone, 556
Interference Fringes, The Quantistic Theory of, E. Fermi, 862
Intergradation between two Subspecies, Analysis of a Concrete Case of (2), F. B. Sumner, 467
Intermetallic Compound, An, having a Simple Cubic Lattice, A. Osawa, 14
International : Baltic Geodetic Commission, Berlin Session of the, 887 ; Committee on the History of Sciences, An, Dr. C. Singer elected president, 283 ; Ellipsoid of Reference, The, G. Perrier, 780 ; Fisheries Investigations, 322 ; Physiological Congress, The Thirteenth, 557 ; Temperature Scales, W. F. Roeser, 891
Invalid Patents, The Grant of, 713
Invariant Theory of two Quadratics in n Variables, Further, Prof. H. W. Turnbull and J. Williamson, 826
Invertebrates, Internal Secretion in, G. Koller, 705
Iodine : Liberator from Laminariæ, An, Dr. G. Lunde and K. Closs, 578 ; Monatomic, and Molecular Hydrogen, W. D. Bancroft and D. S. Morton, 395
Ionisation : Balance of the Atmosphere over Heligoland, The, V. F. Hess, 287 ; Potentials and Conductivities of Metals, Prof. B. B. Ray and D. P. Roychaudhuri, 512
Ionised Air, The Cylindrical Field in, at the Ordinary Pressure, Pauthenier and Mollard, 1007
Ionising Particles, Counting, Hoffmann and Pose, 598
Ions : in Gases, The Mobility of, R. J. Van de Graaff, 10 ; Produced by Discharge at Liquid Surfaces, Prof. J. J. Nolan and J. G. O'Keeffe, 933 ; The Exchanges of, between Yeast Cells and Solutions of Ammonium Chloride, P. Genaud, 77
Iosene, a New Hydrocarbon from Styrian Brown Coal, A. Soltys, 745
Ipswich Museum, J. Reid Moir elected president of the, 594
Iraq, Proposed School of Archæology in, 769
Irish : Radium Committee Report for 1928, 285 ; Winter Butter, The Composition of, P. S. Arup, 602
Iron : and Steel : Institute, award of the Williams Prize to W. E. Simons, 853 ; Photomicrographs of, E. L. Reed, 401 ; The Metallurgy of, 401 ; Roofs in the Tropics, Ventilation of, F. C. Cawston, 897 ; Silicates, The Oxidation and Reduction of the, by Gases, B. Bogitch, 826 ; The Anodic Behaviour and Passivity of, in Sodium Sulphate Solutions, W. J. Müller and W. Manchu (11), 1007
Irradiation and Health : Ultra-Violet Irradiation of School Children ; of Varicose Ulcers, Dora Colebrook, 952
Isomers, The Comparative Stability of, according to their Absorption Spectra, Mme. Ramart-Lucas, 969
Isomorphism and Homology, Sir P. C. Rây, 480
Isotope Effect in Spectra, and precise Atomic Weights, W. F. Giauque, 265
Italia, The Tragedy of the : With the Rescuers to the Red Tent, D. Giudici, 124
Italian : Earthquake of Mar. 27, 1928, Prof. A. Cavasino ; Prof. M. Gortani, 706 ; National Experimental Tank, at Rome, The, 818 ; Somaliland, Magnetic Survey of, Prof. L. Palazzo, 280

Jacobi's Equation, Integrating Factors and, J. P. Dalton, 431
Jamaica, Miocene Mollusca from, W. P. Woodring, 706
Japan, Electric Power in, 668
Japanese : Bryozoa, Yaichurô, 961 ; Calcareous Sponges, Prof. S. Hôsawa, 890
Java : Work of the Dutch in, Prof. G. Elliot Smith, 956 ; Zoogeography of, Dr. K. W. Dammerman, 819
Jealott's Hill Research Station, H. V. Garner, 38
J-phenomenon in X-rays, The, N. S. Alexander, 1006
Junior Schools, Courses of Study in, Memoranda of, 710
Jupiter : Rev. T. E. R. Phillips, 888 ; Changes on, 854 ; General Perturbations of Minor Planets by, 495 ; Occultation of, by the Moon on Oct. 28, 1928, 704

Kalki : or the Future of Civilisation, S. Radhakrishnan, 174
Karroo Reptilia from Madagascar, S. H. Haughton, 78
Katharometer, The, in Gas Analysis, Cambridge Instrument Company, Ltd., 740
Kekulé, The Work of, Prof. H. E. Armstrong, 630
Kelvin : Effect at Low Temperatures, G. Borelius, W. H. Keesom, and C. H. Johansson, 820 ; Kelvin Lecture, Dr. G. C. Simpson, 801, 814 ; Medal : award of the, to A. Blondel, 65 ; presentation, to A. Blondel, 664

Kent, Search for an Oil-Pool in, H. B. Milner, 730
Kenya : Biology of Lakes in, Penelope M. Jenkin, 574 ; Colony, Forestry in, 893
Keto-acidoses, Interpretation of the Values for the Alkaline Reserve of the Blood Plasma in the Course of the, P. Cristol, 42
Kew, Royal Botanic Gardens, Gift of a New Sundial to the, by Prof. C. V. Boys, 965
Kimberlite Pipes and Sub-crustal Rocks, Dr. P. A. Wagner, 280
King Senior Medal and Junior Prize, Foundation of, by S. G. King, 39
Kintyre, The Metamorphic Rocks of, W. J. McCallien, 251
Kleinsten Wirkung, Das Prinzip der, von Leibniz bis zur Gegenwart, Prof. A. Kneser, 124
K-lines of Copper, Wave-length of the, using Ruled Gratings, J. A. Bearden, 467
Klingenberg Power Station, The, 493
Kontinente und Ozeane, Die Entstehung der, Prof. A. Wegener. Vierte Auflage, 649
Korannas, Australoid Element in the, Dr. R. Broom, 507
Kosmischen Physik, Probleme der, Herausgegeben von Prof. C. Jensen und Prof. A. Schwassmann. Band 2 : Das Zodiakallicht, Dr. F. Schmid, 123
Kriegsschauplätze, Die, 1914–1918 geologisch dargestellt. In 14 Heften. Herausgegeben von Prof. J. Wilser. (Heft 6 : Reims, La Fère und Ardennen. Von Dr. C. Schnarrenberger. Heft 7 · Artois und Hennegau. Von Prof. H. Stille. Heft 10, Teil 2 : Bodenschätze im Ostbaltikum (Ostbaltikum, Teil 3). Von Dr. C. Gäbert und Prof. H. Scupin. 539
Kryptogamenflora für Anfänger : eine Einführung in das Studium der blütenlosen Gewächse für Studierende und Liebhaber. Begründet von Prof. G. Lindau. Fortgesetzt von Prof. R. Pilger. Band 1 : Die höheren Pilze. Basidiomycetes, mit Ausschluss der Brand- und Rostpilze. Von Prof. G. Lindau. Dritte Auflage völlig neu bearbeitet von Prof. E. Ulbrich, 403
Krypton, Spectrum of, W. F. Meggers, T. L. de Bruin, and C. J. Humphreys, 498

Lambay, Co. Dublin, Antiquities from, Prof. R. A. S. Macalister, 596
Laminariæ, An Iodine Liberator from, Dr. G. Lunde and K. Closs, 578
Laminated Glasses, W. R. Lyttelton, 161
Lampreys and their Ways, Prof. S. H. Gage, 667
Lancashire Witches, The, 678
Lancaster Witches, The Trial of the, A.D. MDCXII. Edited with an Introduction by G. B. Harrison, 678
Landwirtschaft, Handbuch der, Herausgegeben von Fr. Aereboe, J. Hansen und T. Roemer. Fünf Bände. Lief. 8, Band 1 ; Lief. 9, Band 2 ; Lief. 10, Band 4 ; Lief. 11, Band 2 (Schluss) ; Band 3, 569
Lankester's 'Gregarine' from the Eggs of *Thalassema neptuni*, Prof. D. L. Mackinnon and H. N. Roy, 877
Lanthanum : Monoxide, The Band Spectrum of, Dr. W. Jevons, 41 ; Oxide of, New Bands in the Spectrum of, G. Piccardi, 129
Larix, The Species of Larch, and their Geographical Distribution, C. H. Ostenfeld, 43
Larval Ascidians, Influence of Light on, C. Grave, 889
Laterite, Fossil, from Southern Queensland, W. H. Bryan, 512
Lead : Azide Detonators, Testing of, J. A. Cresswick and S. W. E. Parsons, 898 ; Chloride, Action of Alkaline Carbonates on, Mme. N. Demassieux, 466 ; Molten, Handling, Capt. E. H. Gregory, 760 ; The Second Spark Spectrum of, A. S. Rao and Dr. A. L. Narayan, 794
League of Nations Intellectual Co-operation Committee, Report of the, 673
Lebombo, The Volcanic Belt of the—a Region of Tension, A. L. du Toit, 166
Lechers, E., Lehrbuch der Physik : für Mediziner, Biologen und Psychologen. Fünfte Auflage, 542
Leeches from Sarawak, J. P. Moore, 353
Leeds University : Dr. Ll. Lloyd appointed reader in entomology and protozoology, 164 ; Department of Pathology and Bacteriology, Report for 1928, 277 ; theses approved for research degrees, 284 ; Department of Coal Gas and Fuel Industries, Annual Report of the, 385
Legumes, The Food Value of, studied with Albino Rats, A. Galamini, 168
Leguminosæ, Shelled Seeds of, The Bending of Roots and Hypocotyls of, J. Kisser and R. Stasser, 827
Leicester Museum and Art Gallery, Annual Report of the, 630
Lembang Observatory, Java, The New Equatorial at the, Dr. A. Gradenwitz, 386
Lepidoptera, Tropisms and Sense Organs of, Dr. N. E. McIndoo, 209
Lepisma domestica, Spermatogenesis of, Effect of X-radiation on the, R. N. Mukerji, 780
Leucite-Diopside, The System, Bowen and Schairer, 774
Leucocytes : isolated from the Organism, Action of certain Alkaloids on, C. Forti, 168 ; On Living, J. H. Ferguson, 638
Leukochloridium paradoxum, Biology of, C. Wesenberg-Lund, 42
Lewis's Medical and Scientific Circulating Library, Catalogue of, 277
Lichtelektrische Erscheinungen, Prof. B. Gudden, 572
Life : The Meaning of, as shown in the Process of Evolution, C. E. M. Joad, 571 ; The Mechanism of, Sir J. C. Bose, 103 ; The Mystery of, Prof. A. V. Hill, 557 ; The Nature of, General J. C. Smuts, and others, 205 ; What is, 397
Light : an Introductory Text-Book, C. G. Vernon, 87 ; Periodicity and Plant-Growth, G. Reddington, 108 ; The Absorption of, by the Coloured Globules in the Retina of the Domestic Hen, Prof. H. E. Roaf, 780 ; The Scattering of, in Colloidal Solutions and Gels, K. Krishnamurti, 690 ; Three Aspects of, Prof. W. Peddie, 751
Lighting, Influence of, on the Precision of Movements in the course of Professional Work, R. Faillie and M. Lagarde, 42
Lightning : Dr. G. C. Simpson, 801, 814 ; Progressive, Prof. C. V. Boys, 54 ; Protection from, 212
Lignin, On, A. Friedrich and A. Salzberger, (5), 827
Limnæidæ and their Allies, Resistance of, to Desiccation, Dr. Cawston, 353
Linear Pentacene Series, The, G. Machek (18), 1007
Liquid : -Solid Interface Tension, Dr. M. Loewenthal, 301 ; Veins, The Contraction of, M. Lelli, 862
Liquids, the Refractivity and Dielectric Behaviour of, Influence of Molecular Form and Anisotrophy on, K. S. Krishnan, 825
Lithuania, *Planaria alpina* in, Prof. P. B. Sivickis, 579
Littorina littorea Linn., A Habit of the Common Periwinkle, D. P. Wilson, 443
Liverpool University : Opening of the : New Veterinary Hospital, 39 ; Lady Herdman Geological Laboratories, 669
Livingstone, David, The Scottish National Memorial to, 592
Locomotive : Firebox Stays and Plates, O. F. Hudson, T. M. Herbert, F. E. Ball, and E. H. Bucknall, 466, 709 ; Performance, E. C. Poultney, 211
Lockyer, Norman : and the Total Solar Eclipse of 1875, Sir Arthur Schuster, 838 ; Prof. H. Dingle, 839 ; Lecture, Sir Walter Morley Fletcher, 795, 865
Locust Problem, The : Dr. G. H. Skaife, 471 ; Dr. A. D. Imms, 950
Locusts : and Grasshoppers : a Handbook for their Study and Control, B. P. Uvarov, 471 ; Parasites and Periodicity of, N. G. Olsoufiev, 773
Logarithmetica Britannica : being a Standard Table of Logarithms to Twenty Decimal Places, Dr. A. J. Thompson. Part 4, 721
Logik, theoretischen, Grundzüge der, Prof. D. Hilbert und W. Ackermann, 296
London : and Paris Railway Scheme, The, W. Collard, 383 ; County Council, Robert Blair fellowships awarded to C. G. Davies and G. L. Riddell, 213 ; Mathematical Society, Election of officers, 853 ; New Social Survey of, Sir H. Llewellyn-Smith, 632 ; School of : Economics : L. C. Robbins appointed professor of economics at the, 165 ; C. Manning appointed

Cassel professor of international relations at the, 710; School of Hygiene and Tropical Medicine: The, 162; Fifth Annual Report, 895; Underground Railways, The Heating of the Headquarters of the, 552; University: Sir Gregory Foster elected Vice-Chancellor; conferment of doctorates, 75; conferment of doctorates; award of the University studentship in physiology to Miss Margaret Hill; grants by the Chadwick Trustees, 165; classification of doctorates conferred, 393; New Observatory of the, 601; Dr. E. Deller appointed principal, 743; conferment of doctorates; Miss I. W. Busbridge awarded the Sir John William Lubbock Memorial Scholarship prize, 778; Oriental Studies, School of, foundation of a lectureship in Iranian studies, 824; Dr. G. A. Harrison appointed reader in chemical pathology at St. Bartholomew's Hospital Medical College; conferment of doctorates; Earl Beauchamp installed as Chancellor, 860; the title of emeritus professor conferred on Drs. E. A. Gardner and F. W. Oliver; conferment of doctorates, 1004

Lophius piscatorius, Feeding Habits of the Angler-fish, H. C. Chadwick, 337

Lorentz Electron, The Motion of a, on a Wave Phenomenon, Prof. A. M. Mosharrafa, 726

Lorne Pierce medal of the Royal Society of Canada, presentation of the, to Mgr. Camille Roy, 110

Lo Surdo Fields, Production of High, Prof. Y. Ishida and S. Hiyama, 129

Loughborough College Calendar for 1929–30, The, 429

Love Waves of Short Wave-length, R. Stoneley, 113

Low: Frequency Sound Waves and the Upper Atmosphere, E. H. Gowan, 452; Temperature Carbonisation: of Coal, 852; in Power Station Practice, Prof. P. Rosin, S. McEwen, E. H. Smythe and E. G. Weekes, 1002; The Technology of, F. M. Gentry, 2; -Veld: The, its Wild Life and its People, Lieut.-Col. J. Stephenson-Hamilton, 438

Lower Atmosphere, Temperature Changes in the, N. K. Johnson, and others, 160

Lumineszenz-analyse im filtrierten ultravioletten Licht: ein Hilfsbuch beim Arbeiten mit den Analysen-Lampen, Prof. P. W. Danckwortt, 224

Lymph-heart Beats, On recording, Prof. W. A. Jolly, 115

Lyrid Meteors, Period of the, 158

Macacus rhesus, Modifications of the Blood Coagulation in the course of Experimental Yellow Fever in, J. Vellard and M. Vianna, 745

Macedonia, Prehistoric, W. A. Heurtley, 671

Machinery, Remarkable, The Book of, E. Hawks, 52

Macrolycus Waterh. (Coleoptera Lycidæ), a New Species of the Genus, V. Barovskij, 358

Madras, Flora of the Presidency of, J. S. Gamble. Part 8, by C. E. C. Fischer, 440

Magic: and Witchcraft, 521; Island, The, W. B. Seabrook, 521

Magician and Leech: a Study in the beginnings of Medicine, with Special Reference to Ancient Egypt, W. R. Dawson, 543

Magnesium: Hydride II., The Ultra-violet Spectrum of, R. W. B. Pearse, 41; Oxide, Band Spectrum of, Prof. P. N. Ghosh, B. C. Mookerjee, and P. C. Mahanti, 303

Magnetic: Field of the Sun, General and External, The, Dr. H. Deslandres, 745; Flux: Anomalous, V. Mitkevic, 286, 324, 394; The Transformations of, 286; Guidance of Ships, The, E. Fournier, 861; Intensity and Declination, A New Method of Observing Diurnal Variation of, using Field Instruments, E. N. Grindley, 431; Reaction of the Glowing Filaments of Carbon Incandescent Lamps, the Letter of C. W. Marshall on, The, 817; Storms and Radio Signals, Miss I. J. Wymore, 109

Magnetism of Sun and Earth, Origin of, R. Gunn, 426

Magnetostriction of Diamagnetic Substances in Strong Magnetic Fields, Dr. P. Kapitza, 53

Magnetostrictive Oscillators at Radio Frequencies, J. H. Vincent, 41

Malaria: Discoveries connected with, Letters from Rome on certain, Dr. T. E. Charles and others, with a Preface and Remarks by Sir Ronald Ross, 976; in ihrer Bedeutung für die Geschichte Roms und der römischen Campagna: Die, eine kultur-historische Studie, Prof. A. Celli. Herausgegeben von Anna Celli-Fraentzel, 570; in the Roman Campagna, 570; Studies on, Sir Ronald Ross, 976

Malay Peninsula, Fresh-water Fauna of the, C. Dover, 499

Male Sexual Hormone, Preparation, Properties, and Testing of a, S. Loewe and H. E. Voss, 971

Mallee, Floristics and Ecology of the, J. G. Woods, 897

Malt, Green, Proteolytic Enzymes in, C. K. Mill and K. Linderstrøm-Lang, 210

Malta: Archæology of, 719; Excavations in, M. A. Murray. Part 1, with a Chapter by G. Caton-Thompson. Part 2, with a Chapter by G. Caton-Thompson. Part 3, with a Chapter by C. A. Mitchell and T. J. Ward, 719

Mammalian Life in High Latitudes, R. W. Gray, 228

Mammals, Abnormal Teeth in, Prof. W. C. McIntosh, 927

Man, Inheritance in, Materials for the Study of, F. Boas, 532

Manchester: The Soul of, Edited by Dr. W. H. Brindley, 909; University: N. F. Mott appointed lecturer in mathematical physics; Dr. Miriam K. Bishop and I. Thomas awarded Grisedale Scholarships, 213; Miss Barbara Colson appointed assistant lecturer in botany; R. Whitehead, demonstrator in pathology; C. Handford, lecturer in metallurgy and assaying; B. J. Tams, assistant lecturer in mechanical engineering, 637; impending retirement of Prof. F. E. Weiss, 824; appointment of research fellows, 895

Manganese: A High-temperature Modification of, E. Persson and E. Öhman, 333; Allotropes of, High Temperature, Dr. Marie L. V. Gayler, 840; Dioxide, The Precipitation of, by Electrolysis with an Alternating Current, A. P. Rollet, 252; in Foodstuffs, Newcomb and Sankaran, 35; in Insects, A. P. Vinogradov, 358; in South Africa, L. T. Nel, 425

Manna, The Biblical, Dr. F. S. Bodenheimer and Dr. O. Theodor, 1003

Marine: Biology in Ceylon, Dr. J. Pearson, 742; Engineering, The Trend of, Engr. Vice-Admiral Sir Robert Dixon, 958; Invertebrates, Keeping and Rearing, Dr. G. Grimpe, 352; Life in Pacific Ocean, Unusual Northward Movement of, C. L. Hubbs and L. P. Schulze, 773; Trematodes, Life-histories of, O. R. McCoy, 774; Zoological Stations and Fisheries Institutes on the Coasts of the North Sea and Baltic, The, Dr. H. C. Redeke, 422

Marriage: 648; Ideal, its Physiology and Technique, Dr. T. H. van de Velde. Translated by Stella Browne, 648

Mars: A. Nodon, 704; The Satellites of, H. E. Burton, 665

Martinsel Steel, P. G. Rouse, 247

Materials used in Research, The Authentication of, Prof. H. H. Rusby, 593

Mathematical: Congress, International, Proceedings of the, held in Toronto, August 11-16, 1924. Edited by J. C. Fields. 2 vols., 255; Notations, A History of, Prof. F. Cajori. Vol. 1: Notations in Elementary Mathematics, 4; Physics, Decay Problems in, Dr. M. Strutt, 230

Mathematics: and Life, Prof. J. Maclean, 214; Pure, Prof. L. M. Milne-Thomson, 683; A Course of, Prof. G. H. Hardy. Fifth edition, 683; The Application of, Prof. J. Maclean, 735; The March of, Prof. A. W. Conway, 255

Mathematik, Geschichte der, Quellen und Studien zur, Herausgegeben von O. Neugebauer and others. Abt. B. Band 1, Heft 1, 540

Matter: Electricity, Energy: the Principles of Modern Atomistics and Experimental Results of Atomic Investigation, Prof. W. Gerlach. Translated by Dr. F. J. Fuchs, 176; Life and Value, C. E. M. Joad, 979; The General Properties of, Prof. F. H. Newman and V. H. L. Searle, 527

Mayon Volcano, The Eruptions of, L. A. Faustino, 856

Mecca, Westward to, Sirdar Ikbal Ali Shah, 539

Mechanical: Aptitude: its Existence, Nature, and Measurement, J. W. Cox, 757; Engineers, Institution of, Presidential Address to the, Dr. D. Adamson, 661; Inventions, A History of, Prof. A. P. Usher, 905;

Science, The Contribution of Manchester Researches to, R. W. Bailey, 67
Mechanics: and Acoustics, 330; Theoretical, Prof. L. M. Milne-Thomson, 331; The Principles of, an Elementary Course, Prof. H. C. Plummer, 331
Medical: Adventure: some Experiences of a General Practitioner, Dr. E. Ward, 910; Education, Methods and Problems of, No. 12, 886; Research: Council, appointment to the, of Viscount D'Abernon, Major A. G. Church, Prof. J. J. R. MacLeod, and W. Trotter, 276; The Tree and the Fruit, Sir Walter Morley Fletcher, 795, 865; Works, Distribution of, William Heinemann (Medical Books), Ltd., 728
Melanins from Adrenaline, P. Saccardi, 674
Melanophore Activator of the Eye, The, B. Kropp, 898
Melchett research scholarship in surgery, Foundation of, by Lord Melchett, 627
Mellon Institute, The Industrial Fellowships of the, at Pittsburg University, 1928–29, 996
Mendelian Mutants, Fossil Records of, Capt. C. Diver, 183
Mendélienne, Principes et formules de l'hérédité, Prof. L. Blaringham, 407
Mengenlehre, Einleitung in die, Prof. A. Fraenkel, 8
Mental Defectives and their Order of Birth, N. A. Dayton, 159
Mercury: Arc Rectifiers, 462; Line 1849·57 ($1^1S_0 - 2^1P_1$), Behaviour of the, Prof. A. T. Williams, 985
Mesopotamian Culture, Early, H. Field; Prof. S. Langdon, 156
Metal: and Timber in Sea-Water, Preservation of, Dr. J. N. Friend; Prof. G. Barger, 498; Single-crystals of, A Method of Producing Long, A. Goetz and M. F. Hasler, 675
Metallic: Films, Thin, Recent Experiments on, M. Pierucci, 638; Resistance of 10^{10} to 10^{11} Ohms, A, E. Perucca, 781; Sulphides, Action of High Temperatures on some, Picon, 286
Metallography, Research in, G. Masing, 430
Metallurgia, No. 1, 959
Metallurgy, Physical, Research on, Dr. W. Rosenhain, 430
Metals: Bivalent, The Crystalline Structure of Bromides of, A. Ferrari and F. Giorgi, 674; Electrical Resistance in, Sir Oliver Lodge, 634; Institute of, Journal of the. Vol. 41. Edited by G. S. Scott, 649; Passivity of, Optical Investigations of the, L. Tronstad, 373
Meteor, A Flashing, W. F. Denning, 423
Meteoric Stone of Lake Brown, Western Australia, The, Dr. G. T. Prior, 76
Meteorological Science To-day, Sir Napier Shaw, 771
Meteorologists, Empire, Conference of, 427
Meteorology: Antarctic, 967; in British East Africa, A. Walter, 283; in India, Dr. C. W. B. Normand; The Writer of the Article, 335
Meteors: July and August, W. F. Denning, 106; Large, J. Stokley; Prof. C. P. Olivier; Dr. W. J. Luyten, 158; Telescopic Bielid, Prof. C. P. Olivier, 278
Methyl: and Ethyl Alcohol, The Dissociation of Acids in, D. M. Murray-Rust and Sir Harold Hartley, 825; Free, Existence of, Panneth and Hofeditz, 161
Methylene Iodide, Action of the Zinc-copper couple on, G. Emschwiller, 114
Mexican Earthquake Sea-Waves of June 16, 1928, Hilo, 633
Mice and Evolution, N. Dobrovolskaïa-Zavadskaïa, 855
Micellary Equilibria and Membrane Equilibria, J. Duclaux and R. Titeica, 286
Micro-organisms in a High Vacuum, Lethal Action of Ultra-Violet Light on, Dr. D. A. Wells, 693
Microscope, New Model, C. Baker, 319
Migrations of Sea Animals to Land, A. S. Pearse, 961
Milk, Composition of, Variations in the, 705
Millilitre, The, V. Stott, 622
Mimicry, Dr. G. D. Hale Carpenter, 183
Mineral: hitherto Unrecognised in the Phonolites of Dunedin, New Zealand, A. P. Marshall, 76; Metabolism: Iodine and Sulphur, 95; of the Astrophyllite Group, A, from the Mountain Urma-Varaka, B. Kupletskij, 395
Mineralogical Society, Election of Officers, 771
Mineralogy at Cambridge, 45
Minerals: and Animal Nutrition, Prof. T. B. Wood, 437; in Pastures and their relation to Animal Nutrition, Dr. J. B. Orr, with the assistance of Helen Scherbatoff, 437; The International Relationship of, Sir Thomas Holland, 187
Mines: The Ventilation of, Generation of the Air Current, Prof. H. Briggs, 537; Workings in, Support of, Fifth Report, 420
Mining: Electricity applied to, H. Cotton, 538; Engineers, Institution of, award of the medal of the, to G. S. Rice, 316; Explosives, Modern, 1002; Subsidence, Prof. H. Briggs, 537
Miocene Mollusca of Virginia and North Carolina, W. C. Mansfield, 108
Mitogenetic Rays, Action of the, through a Quartz Screen, A. Naville, 602
Mitosis, Effect of Low Temperature on, G. F. Spear, 33
Mnium cuspidatum, Changes occurring in the Cytological Structure and some Physiological Processes in the Cells of, under the influence of Dehydration, I. E. Znamenskii, 286
Modern Faith, G. G. Coulton, 959
Mohn Bay, on the East Coast of Spitsbergen, The Fauna of a Bed at, V. I. Bodylevskij, 359
Molecular: Air-Pumps, Prof. E. N. da C. Andrade, 657; Spectra and Molecular Structure, Prof. W. E. Garner and Prof. J. E. Lennard-Jones, 584, 762; Structure: Infra-Red Analysis of, F. I. G. Rawlins and A. M. Taylor, 789; Infra-Red Investigations of, C. P. Snow and Dr. C. K. Rideal (3 and 4), 825
Molecules from ordinary Hydrogen, Two Kinds of, Dr. Bonhoeffer, 455
Mollusca of the Irish Atlantic Slope, The, Miss A. L. Massy, 933
Molophilus (Tipulidæ, Diptera), The Australian Species of, C. P. Alexander, 287
Monocalcium Aluminate in Solution, The Existence of, A. Travers and Schnoutka, 358
Monzonitic and Nepheline-bearing Rocks of Mount Dromedary, N.S.W., Ida A. Brown, 287
Moon: Future of the, Dr. H. Jeffreys, 317; Romance of the, Mary Proctor, 405; The Story of the, G. P. Serviss, 405
Moose auf genetischer Grundlage, Morphologie und Physiologie des Formwechsels der, II., F. von Wettstein, 175
Moray Firth: Line Fishing in the, Dr. A. Bowman, 387; Trawling in the, 460
Moroccan: Recurrent Spirochætes of the *hispanicum* Group are not separable into Species, The, C. Nicolle and C. Anderson, 1007; Spirochætes of the Ornithodores from Burrows and the Spirochæte of Mansouria are not Recurrent in Man, The, P. Delanoë, 503
Morphological Characters depending upon External Conditions, Two New Examples of, M. Molliard, 826
Morphology, Contributions to the Principles of, Dr. W. B. Crow, 720
Mortar Strength, Influence of Aluminium on, H. W. Leavitt, J. W. Gowen, and L. C. Jenness, 898
Mortimer Museum, Hull, Opening of the, by Sir Frederic G. Kenyon, 853
Mosquito Larvæ, Development of, Dr. M. E. MacGregor, 855
Motor: Benzene, A Method of Testing, R. Brunschwig and L. Jacque, 780; Fuel, Research on, 635; Ship, The Progress of the, Engr.-Capt. E. C. Smith, 307; Transport: The Problem of, an Economic Analysis, C. T. Brunner, 124
Mouches parasites, Études sur les. Tome 1: Conopides, Œstrides et Calliphorines de l'Europe occidentale, E. Séguy, 572
Moulds, The Growth of, B. G. Tomkins (1), 780
Mount: Passa, The Geological Profile of, at the Cataractes Plateau, M. Gysin, 394; Wilson, Silvering the 100-inch Mirror at, R. W. Porter, 423
'Mountain Beavers' of America, T. H. Scheffer, 819
Mouse Placenta, Presence of a Kuogenic Substance in the, L. Mirskaja, 826
Mucic Acid, Some Optical Properties of, M. Gysin, 78
Mucor, Sensitivity to the Ultra-violet in, as a Function of Age, B. Luyet, 215

Mucors, Bread Moulds, Criteria of Male and Female in, Sophia Satina and A. F. Blakeslee, 898
Müller-Pouillets Lehrbuch der Physik. Elfte Auflage. Herausgegeben von A. Eucken, O. Lummer, E. Waetzmann. In 5 Bänden. Band 1 : Mechanik und Akustik. Teil 1 : Mechanik punktförmiger Massen und starrer Körper. Herausgegeben von E. Waetzmann. Teil 2 : Elastizität und Mechanik der Flüssigkeiten und Gase. Herausgegeben von E. Waetzmann. Teil 3 : Akustik. Bearbeitet von E. Waetzmann, 330
Mummification of the Ancient Egyptians, A. Tulli, 674
Munitions of War, 607
Müntz Methods of Nitrification, The, A. P. Forjas, 826
Muscle Plasma, The Coagulation of, E. C. Smith, 780
Muscular Sense, Existence of the, Subjective Demonstration of the, Prof. D. F. Fraser-Harris, 794
Museum of Science and Industry in Chicago, A proposed, 924
Museums : and Galleries, National, Royal Commission on, Final Report, part 1, 749 ; Association : Annual Conference of the ; Presidential Address of, Sir Henry Miers, 73 ; election of Dr. F. A. Bather as an honorary member, 68 ; Report, The, and National Folk Museums, 901
Mycology : Contributions to, Dame Helen Gwynne-Vaughan, and others, 820 ; Imperial, 729
Mycoses of the Epidermis, P. Vuillemin, 744
Myoprotein, Molecular Weight of, Determined by Du Noüy's Surface Tension Method, L. De Caro, 638
Myrica Gale, The Phenomena of Symbiosis in, P. A. Dangeard and Mme. Mara Lechtova Trnka, 166
Myristic Acid, Superficial Layers and Superficial Solutions of, F. Emir, 215
Mysore Tribes and Castes, The, the late H. V. Nanjundayya and Rao Bahadur L. K. Ananthakrishna Iyer. Vol. 2, 788
Myxosporidæ, Gametes and Gonomery in the, Sexualisation of the, A. Naville, 602

Nant Peris and Nant Ffrancon (Snowdonia), The Geology of the Country between, D. Williams, 932
Naphthenic Acids, Hydrolysis and Cracking of, at High Temperatures and under High Pressure, V. N. Ipatiev and A. D. Petrov, 286
Nation, The, and Research, 865
National : Institute for the Blind, Report of the, 771 ; Museum for England, A proposed, 155 ; Museums : and Galleries, Royal Commission on : Interim Report of the, 661 ; Final Report, Part 1, 749, 937 ; The, and Education, 937 ; Parks in Great Britain, appointment of a committee upon the possibilities of establishing, 590 ; Physical Laboratory : Annual Report for 1928, 553 ; Inspection by the General Board, 36 ; Radium : Fund and National Radium Commission, A Charter granted, 104 ; Trust, appointment of a secretary and assistant secretary, 243 ; Surveys, Brigadier E. M. Jack, 487
Native : Education in Africa, 829 ; Policy in Africa, General Smuts, 816
Natrolite from Viagrande (Etna), S. Di Franco, 115
Natural : History : and Folk-Lore, C. Oldham ; L. Rowland, 229 ; Society of Northumberland, Durham, and Newcastle-upon-Tyne, Report of the, 770 ; Ionising Radiation and Rate of Mutation, Profs. E. B. Babcock and J. L. Collins, 227 ; Selection : Prof. E. W. MacBride, 225, 689 ; Prof. W. Garstang, 410 ; J. B. S. Haldane, 444
Nature Reserves in Soviet Russia, 663
Nautical Almanac, The, and Astronomical Ephemeris for the Year 1931 for the Meridian of the Royal Observatory at Greenwich. Standard edition, 835
Navajo, The, Miss Gladys A. Reichard, 460
Naval Architects, Institution of, award of scholarships, 710
Navy, Health of the, Statistical Report of the, 316
Naval Wireless Telegraph Communications, G. Shearing and Capt. Dorling, 967
Neanderthal Woman, Discovery of the Skull of a, near Rome, Prof. S. Sergi, 995
Nebula in Andromeda, The, Dr. E. Hubble, 244
Nederlandsch Instituut voor Documentatie en Registratuur, Mededeelingen van het. No. 6, 1928. 10/12, 942
Needle Galvanometer, A suggested New Type of Sensitive, Suspended, Dr. J. H. J. Poole, 295
Negro Mortality, Biological Factors in, Prof. R. Pearl, 663
Neogene Shells from Japan, Prof. M. Yokoyama, 319
Neon : in Natural Gases, The Quantitative Determination of, N. P. Péntcheff, 466 ; Isotopes, Prof. Nagaoka and T. Mishima, 354
Nerve : Centres, Mechanism in, Prof. A. Forbes, 911 ; Trunks, Action of Alkaloids of the Cocaine Type on the, J. Régnier, 466
Nervensystems der wirbellosen Tiere : Vergleichende Anatomie des, unter Berücksichtigung seiner Funktion, Dr. B. Hanström, 368
Nervous System, Unitary Behaviour of the, Prof. F. Allen, 279
Neurasthenia, A Challenge to, Doris Mary Armitage, 944
Neurology, Recent Advances in, W. R. Brain and E. B. Strauss, 755
Newcomen : Thomas : The Bicentenary of, 184 ; Two Hundred Years of Steam Power, Eng.-Capt. E. C. Smith, 206 ; Eulogy on the Work of, L. St. L. Pendred, 206 ; Society : Summer Meeting of the, 205 ; Transactions, vol. 7, 1926–1927, 528 ; L. St. L. Pendred to retain presidency, 853
New South Wales : History of Igneous Action in, until the Close of the Palæozoic Era, W. R. Browne, 286 ; Royal Zoological Society of, Jubilee of the, 242
Newton, Sir Isaac : A hitherto Unpublished Letter of, 29 ; Books from the Library of, 29 ; "System of the World", The translator of, Prof. F. Cajori, 513
New : York City Air, Dust in, 210 ; Zealand : Earthquake of June 17, 1929, H. T. Ferrar and L. I. Grange ; H. E. Fyfe, 1000 ; Late Cretaceous and Tertiary of, Dr. J. Henderson, 856 ; Tertiary Mollusca, Dr. J. Marwick, 461 ; The Trees of, Dr. L. Cockayne and E. P. Turner, 717 ; The Vegetation of, Dr. L. Cockayne. Second edition, 717 ; Trees and Shrubs : and How to Identify them, Dr. H. H. Allan, 717
Niagara Falls, 555
Nickel : and Cobalt, The Quantitative Analysis of Mixtures of, Dr. S. Glasstone and J. C. Speakman, 969 ; -chromium Alloy, The Creep of 80 : 20, at High Temperatures, A. G. Lobley and C. L. Betts, 431 ; in Engineering, W. T. Griffiths, 823 ; Steels, Low-expansion, T. F. Russell, 598 ; Vapour, The Number of Excited Atoms and the Absorption Spectrum of, Prof. A. T. Williams, 373
Night Sky, The, J. Dufay, 598
Nitric Oxide at 296° K. and 216° K., Magnetic Susceptibility of, F. Bitter, 675
Nitrogen : Afterglow, The, Dr. E. J. B. Willey, 443 ; and Carbon Dioxide, Specific Heat of, High Temperature Determinations of the, M. Chopin, 215 ; Pentoxide, The Rate of Decomposition of, at Moderately Low Pressures, H. C. Ramsperger, M. E. Nordberg, and R. C. Tolman, 467 ; Solid, Crystal Structure of, Prof. L. Vegard, 267, 337 ; Spectrum of, Alternating Intensities in the, F. Rasetti, 792 ; Tetroxide, Rate of Dissociation of, Prof. A. R. Olson and C. E. Teeter, Jr., 444 ; The Heat of Dissociation of, J. Kaplan, 216 ; with Manganese, The Combination of, L. Duparc, P. Wenger, and C. Cimerman, 78
Nobel Prize : for Medicine for 1929, Division of the, between Sir Frederick Gowland Hopkins and Dr. C. Eijkman, 732 ; for Physics for 1928, Award of the, to Prof. O. W. Richardson, 814 ; for Physics for 1929, Award of the, to L. de Broglie, 883 ; for Chemistry for 1929, Award of the, to Prof. A. Harden and Prof. H. von Euler-Chelpin, 815
Noble Gases in Vacuum Tube Discharges, Appearance of D. Dooley, 372
Noise, The Measurement of the, emitted by Stationary Machinery, B. A. G. Churcher and A. J. King, 770
Nomades : essai sur l'âme juive, Kadmi-Cohen, 174
Non-marine Mollusca of Oregon and Washington, J. Henderson, 890
North : American Mammals, Field Book of, H. E. Anthony, 836 ; -east Coast Exhibition at Newcastle-upon-Tyne, The, H. Richardson, 18

Northampton, County of, Survey of Land in the, 242
Northamptonshire and Northern Oxfordshire, The Upper Estuarine Series of, Beeby Thompson, 932
Norway, Construction of a Vessel for Ice Navigation, 243
Norwegian : Herring, Dr. E. Lea, 554 ; Lakes, Biology of, T. Braarud, B. Föyn, and H. H. Gran, 73
Nor'westers, Origin of, Dr. S. C. Roy and G. Chatterji, 481
Novarsenobenzene (Neosalvarsan), Toxicity Tests for, Florence M. Durham, J. H. Gaddum, and J. E. Marchal, 282
Nuclear Spin on Spectra, Effect of, J. Hargreaves, 246

Oahu : Post-Tertiary Marine Mollusca of, J. M. Ostergaard, 71 ; The Coral Reefs of, J. B. Pollock, 34
Observatories of Paris and Meudon, The, 244
Ocean : Currents, Theoretical Investigations of, Prof. V. W. Ekman, 742 ; Surface-Water Temperatures, Sir Frederic Stupart, J. Patterson and H. G. Smith, 210
Oceans, Continents and, Dr. G. C. Simpson, 837, 948
Ocinebra erinacea, Habitats and Feeding Habits of, Prof. J. H. Orton, 370
Oddities : a Book of Unexplained Facts, Lieut.-Comdr. R. T. Gould, 368
Œnothera : A Haploid, Prof. R. R. Gates, 948 ; Chromosome Linkage in, F. M. Sheffield, 497
Official Statistics, Current, Guide to, 630
Ohmic Resistances, The Rapid Calculation of, with Alternating Current, A. Levasseur, 781
Oil : Drilling for, with Diamond Drills, R. T. Banks, 160 ; -fields of Burma, Dr. L. D. Stamp, 71 ; Gas and Water from Wells, Analytical Principles of the Production of, Dr. S. C. Herold. With a foreword by C. F. Tolman and a final summary by E. K. Parks, 644 ; Industry, Laws and the, Sir Arnold Wilson, 885 ; -Pool in Kent, Search for an, H. B. Milner, 730 ; -Pools and Fault-Zones, F. Reeves, 859 ; -Shale, Natural Distillation of, H. W. Hoots, 497
Oils extracted from a given Animal, The Regularity of the Variations of the Characters of, L. Margaillan, 166
Old Red Sandstone of Shetland (north-western area), The, T. M. Finlay, 251
Oleic Acid, Superficial Solutions of, J. Guastalla, 431
Omnibuses, Electrification of, L. Bellingham, 31
Oolitic Iron Minerals, The Bacteriaceæ of the, L. Dangeard, 166
Opalinidæ, The, and their Significance, M. M. Metcalf, 395
70 Ophiuchi, The Binary Star, R. Tschilschke, 854
Ophthalmoscope, A Glare-free, Reflexless, Stereoscopic Hand, A. G. Frewin, 896
Optical : Congress, An, 456 ; Isomers, Clark and Yohe, 775 ; Settings, The Insensibility and Personal Equation Errors of, J. Guild, 1006 ; Telephony by Means of Ultra-violet or Infra-red Rays, Q. Majorana, 638
Orbits in the restricted Problem of Three Bodies, Some Classes of, E. Strömgren, 42
Orchids, certain, Variations in, Rev. H. M. R. Rupp, 971
Ordnance : and Gunnery, Textbook of, Lieut.-Col. E. McFarland, 607 ; Survey, Report of the, 736
Ordovician Ostracoda from Tennessee, S. R. Kirk, 739
Ore : Deposits, Ore-lead and Rock-lead and the Origin of certain, Prof. A. Holmes, 477
Organic : Acids, The Adsorption of, by Charcoal, C. Fromageot, 412 ; Chemistry, Syntheses in, by means of Radiant Energy (3), R. de Fazi, 638 ; Compounds : Cracking of some, under High Pressure in a Hydrogen Atmosphere, V. N. Ipatiev, N. A. Orlov, and N. D. Lichatchev, 286 ; Heats of Combustion of, M. S. Kharasch, 34 ; Irreversible Transformations of, under High Pressures, P. W. Bridgman and J. B. Conant, 675 ; Laboratory Methods, the late Prof. Lassar-Cohn. Translated by Prof. R. E. Oespar. Edited by R. Adams and H. T. Clarke, 535 ; Sulphur Bases, A New Class of, T. G. Levi, 168
Organo : -magnesium Carbonates, True Mixed, D. Ivanoff, 252 ; -metallic Compounds, Replacement of Metals in the, by Hydrogen under High Pressure, V. N. Ipatiev, G. A. Razuvaev, and I. F. Bogdanov, 286
Ornithorhynchus, Skull of, Dr. Kesteven and Mr. Furst, 961
Oscillating Arc, A Phenomenon of the, Prof. W. Cramp and A. P. Jarvis, 913
Osleriana, Bibliotheca, 526
Osler's Library, Dorothea Waley Singer, 526
Osmotic Pressure in some Agricultural Plants, Influence of a Complete Manure on the, E. Blanchard and J. Chaussin, 78
Ottica fisica, Lezioni di, V. Ronchi, 751
Ovarian Hormones, The, Dr. F. H. A. Marshall ; The Writer of the Article, 94
Over-feeding, R. Bonnet and Tchang-Hyao-Tchi, 42
Overseas Education, No. 1, 743
Oxford : Dictionary of Current English, A Concise, adapted by H. W. Fowler and F. G. Fowler from The Oxford Dictionary. New edition, revised by H. W. Fowler, 7 ; University, Prof. R. Robinson appointed Waynflete professor of chemistry, 994
Oxidation : and Reduction, Theory of, Prof. W. A. Noyes, 556 ; -reduction : 247 ; Studies in. W. Mansfield Clark, and others, 213
Oxido-reduction, Changes of Reaction and Phenomena of, observed in the course of the Development of some Fungi, F. Labrousse and J. Sarejanni, 969
Oxygen : A Fluorescence Spectrum of, F. Rasetti, 395 ; Heat of Adsorption of, and Nitric Oxide on Charcoal, H. I. Bull and Prof. W. E. Garner, 409 ; Desiccated, Dielectric Constant of, Riley, 109 ; group, Low Atomic Energy Levels for Elements of the, Prof. J. C. McLennan and M. F. Crawford, 874 ; The Isotopes of, Prof. R. T. Birge, 13
Oyster : Culture in Malaya, C. Dover, 264 ; -drills on English Oyster-beds, The, Prof. J. H. Orton and C. Amirthalingam, 298
Oysters : Hermaphrodite, Prof. P. Pelseneer, 14 ; Monœcious, T. C. Roughley, 793
Ozone : contained in the Upper Atmosphere, Quantity of, D. Chalonge and F. W. P. Götz, 896 ; in the Atmosphere, Dr. D. N. Harrison, 58 ; F. E. Fowle, 71 ; Photosensitised Decomposition of, Prof. A. J. Allmand and J. W. T. Spinks, 651

Pacific, Chart of the, Commdr. J. P. Ault, 319
Palæarctic Orthoptera, E. F. Miram, 167
Palæozoic Glaciation, The late, Dr. G. de P. Cotter, 723
Paleontology, Prof. E. W. Berry, 944
Palladium, Melting-point of : Fairchild, Hoover and Peters, 108 ; F. H. Schofield, 857
Paludisme, La découverte de la transmission du, par les moustiques, Sir Ronald Ross, 976
Pan-Pacific Science Congress, Proceedings of the third, 421
Paper-Making, Modern, R. H. Clapperton and W. Henderson, 613
Papyrus : Alterations produced in the Stem of, by Protozoa, L. Petri, 167 ; Salt, The, Dr. A. M. Blackman, 206
Parachors, The Calculation and Interpretation of, S. A. Mumford and J. W. C. Phillips, 891
Para-Foveal Regions, Influence of the, on the Foveal Region of the Retina, Dr. F. W. Edridge-Green, 877
Paralysis, General, and its Treatment by induced Malaria, Surgeon Rear-Admiral E. T. Meagher, 671
Paramagnetic Salts, Fused, L. A. Welo, 575
Parameters, On the Determination of the, in an Empirical Formula, W. E. Deming, 1006
Parasitic : Autotomy in Worms and its Possible Significance, Mabel Fullegar, 792 ; Worms, The, 261
Paris : École Centrale des Arts et Manufactures, The, 75 ; University, courses in anthropology at, 1005
Park, Mungo, and Richard Lander, The Monument on Jebba Island to, Earl of Scarbrough, 592
Parliament, Science and, J. H. Coste, 728
Parliamentary Science Committee : A, 641 ; Creation of a Non-party, 662
Particles, Small, Aggregation of, H. S. Patterson, Prof. R. Whytlaw-Gray and W. Cawood, 210
Passivity Phenomena, The Theory of, W. J. Müller : and K. Konopicky (9), 1007 ; and L. Holleck (7), 1007

Patent : Law and Practice, A. W. Griffiths, 756 ; Records, Calendar of, 602
Patents, Invalid, The Grant of, 713 ; C. Romer, 874 ; Dr. N. R. Campbell ; The Writer of the Article, 875
Pathology, A History of, Prof. E. R. Long, 543
Pavlov's Collected Addresses, 400
Peat, Low Temperature Carbonisation of, T. Donnelly and Prof. J. Reilly, 1006
Pectic Substances of Plants, The, M. H. Branfoot (M. H. Carré), 709
Pedler, Alexander, Lecture, Dr. G. C. Simpson, 988
'Peking Man', The Antiquity and Evolutionary Position of, Sir Arthur Keith, 628
Pendulum Clock, Escapement Errors of, E. C. Atkinson, 933
Penrose's Annual : the Year's Progress in the Graphic Arts. Edited by W. Gamble, Vol. 32, 981
People of the Twilight, The, D. Jenness, 8
Perfumes, Cosmetics, and Soaps : with special reference to Synthetics, W. A. Poucher. Vol. 2. Third edition, 572
Periodic Precipitations and Diffusion, Prof. H. Ryan and R. J. Doyle, 762
Peripheral Vision, Adaptation in, A Phenomenon of, P. Lazarev, 394
Permeabilitätsproblem : Das, seine physiologische und allgemein-pathologische Bedeutung, Prof. E. Gellhorn, 609
Permeameters, Rods and Strips, C. E. Webb and L. H. Ford, 962
Perseids, The August, of 1929, W. F. Denning, 317
Persian Alchemy, M. Ahmad, 462
Persuasion and Belief, 941
Perú, Geologie von, Prof. G. Steinmann. Mit Beiträgen von R. Stappenbeck : Nutzstoffe ; F. Sieberg : Erdleben ; C. Lissón : Geologische Karte, 943
Petal-colour and Hydrogen-Ion Concentration, Buxton and Darbishire, 319
Petalocrinus Limestone Horizon at Woolhope (Herefordshire), The, R. W. Pocock, 744
Petroleum : and Natural Gas, The Geology of, Prof. E. R. Lilley, 644 ; Chemical Constituents of, Determination of the, E. W. Washburn, J. H. Bruun and M. M. Hicks, 211 ; Cracking, Prof. H. A. Wilson, 35 ; Geology, 644
Petrols, Spontaneous Combustion of, Variation of the Temperature of, to which different Substances have been added, A. Grebel, 286
Pflanzlichen Transpiration, Die physikalischen Komponente der, A. Seybold, 293
*p*H, The Action of, on Striated Muscle, S. Goldberger, 168
Phantom Walls, Sir Oliver Lodge, 941
Pharmaceutical Products, 906
Pharmacognosy : Handbook of, Dr. O. A. Wall, revised by Prof. L. Suppan. Fifth edition, 906 ; Kraemer's Scientific and Applied. Third edition, 906
Phaseolus coccineus Seedlings, The Growth of the Stem Parts in, W. Feldmann, 746
Phenological Observations in the British Isles, Report of the, Dec. 1927 to Nov. 1928, 851
Phenylindene Series, Researches in the, C. Moureu, C. Dufraisse, and P. Gagnon, 431
Philips's Handy Theodolite, G. C. Sherrin, 775
Phlebotomus, Notes on (3), N. Nasonov, 897
Photochemische Versuchstechnik, Prof. J. Plotnikow. Zweite Auflage, 439
Phormia in *Calliphora* Cultures, Appearance of, Prof. E. A. Bogdanov, 962
Phosgene, Molecule of, The Structure and Activation of the, V. Henri and O. R. Howell, 825
Phosphorus : Pentoxide, Action of Ammonia on, Harris and Wooster, 320 ; Trioxide, Preparation of, Wolf and Schmager, 281 ; Vapour, Optical Excitation of, Miss A. Jakovlev and A. Terenin, 337
Photochemical : Reactions, The Temperature Coefficients of some, G. B. Kistiakowsky, 216 ; Temperature Coefficients, W. D. Bancroft and R. P. Allen, 395
Photo-electric : Photometry, a Method of, with a Variable Source of Radiation, T. D. Gheorghiu, 166 ; Thallium Cells, Q. Majorana, 79
Photographic Emulsions : their Preparation and Coating on Glass, Celluloid and Paper, Experimentally and on the Large Scale, E. J. Wall, 981
Photography, Seventh International Congress of, Proceedings of the, July 9-14, 1928, 369
Photometric Chemical Analysis (Colorimetry and Nephelometry), Prof. J. H. Yoe. With contributions to Vol. 2 by Dr. H. Kleinmann. Vol. 2 : Nephelometry, 790
Photosynthesis, The Energetic Efficiency of, Dr. R. Wurmser, 912
Phototropy in Inorganic Compounds, E. Lakshminadha Rao, K. Varahalu, and M. V. Narasimhaswami, 303
Photovoltaic Electromotive Forces, The Influence of Temperature on the, G. Athanasiu, 745
Phrynocephalus, Lizards of the Genus, S. F. Tsarevskij, 969
Phyllophora, Reproduction in the Danish Species of, L. K. Rosenvinge, 42
Physical : Anthropology, Measurements and Landmarks in, Prof. F. Wood Jones, 703 ; Constants, Prof. R. T. Birge, 461
Physics : A Classic of, 119 ; Beyond, Sir Oliver Lodge, 701; in Fuel Problems, Dr. C. H. Lander, 894 ; Introduction to, Prof. L. Page, 527; of the Air, Dr. W. J. Humphreys, Second edition, 981 ; School, A. J. White, 87 ; Theoretical, 527
Physik : ein Lehrbuch für Studierende an den Universitäten und technischen Hochschulen, Prof. W. H. Westphal, 8 ; Handbuch der, Herausgegeben von H. Geiger und H. Scheel. Band 8 : Akustik, Redigiert von F. Trendelenburg, 365 ; Lehrbuch der, in elementarer Darstellung, Dr. A. Berliner, Vierte Auflage, 542
Physiological Congress, The Thirteenth International, 557
Physiologische Zoologie, Einleitung in die (Physikalische und chemische Funktionen des Tierkörpers), Prof. H. Przibram, 757
Physiology : in the Treatment of Disease, Prof. W. E. Dixon, 148 ; Recent Advances in, Prof. C. Lovatt Evans. Third edition, 543 ; the Basis of Treatment, Prof. W. E. Dixon, 201 ; The Progress of, Prof. A. Krogh, 557
Phytophthora in Malaya, Species of, A. Thompson, 318
Picard-Borel, Le théorème de, et la théorie des fonctions méromorphes, Prof. R. Nevanlinna, 542
Pickett-Thomson Research Laboratory, Annals of the, Vol. 4 : The Pathogenic Streptococci : an Historical Survey of their Rôle in Human and Animal Disease. 2 parts, 294
Pictures, Examining, The Methods of, Prof. A. P. Laurie, 969
Piezo-electric quartz, M. Cosyns and R. Moens, 934
Piperonaldehyde, Condensation of, with certain pinocolines, E. Pace, 167
Pisum : A Chromosome Ring in, Eva Richardson, 578 ; *sativum*, the Permeability of the Seed Coats of, for Water and Gases, J. Kisser and R. Windischbauer, 827
Pitcher Plants, Fauna of, C. Dover, 927
Pitman's Technical Dictionary of Engineering and Industrial Science in Seven Languages, compiled by E. Slater. 4 Vols., 978
Pitt-Rivers Museum at Farnham, The, 494
Placenta, Phylogeny of the Primate, G. B. Wislocki, 496
Plaice in Danish Waters, Dr. Blegvad, 554
Planaria alpina in Lithuania, Prof. P. B. Sivickis, 579
Plane : Curves, The Elementary Differential Geometry of, R. H. Fowler. Second edition, 683 ; grating Spectroscopes with Wave-length Drums, E. Häschek, 782
Planet : Interesting New Minor, 737 ; New Minor, 69
Planetary : Figures to the Second Approximation, The, R. Wavre, 602 ; Motion in a Retarded Newtonian Potential Field, R. J. Kennedy, 898 ; Nebulæ, Motions of the, Prof. C. D. Perrine, 998 ; System, Origin of the, Dr. H. Jeffreys, 32
Planets : and Satellites, Periods of, Commensurabilities of, L. W. Topham, 926 ; Free Surface of the, The Second Approximation in the Investigation of the, R. Wavre, 79 ; Inner, The Secular Variations of the Orbital Elements of the, Dr. H. Spencer Jones, 897 ; Major, The Puzzle of the, Prof. H. N. Russell, 351
Plankton : of the Tyne Estuary, Miss O. M. Jorgensen, 667; Research, Nets for, C. Künne, 856
Plant : Cell Membrane, The Permeability of, to Sugar, Prof. R. S. Inamdar and K. V. Varadpande, 875 ; Cytology, New Fixations for, L. La-Cour, 127 ; Diseases, F. T. Brooks, 257 ; Ecology : the Distribu-

tion of Vegetation in the British Isles, arranged on a Geological Basis, Mary A. Johnstone, 332; Growth, Length of Day and, Prof. Maximow; M. A. H. Tincker, 820; in Relation to Water, The: A Study of the Physiological Basis of Drought Resistance, Prof. N. A. Maximov, translated by Prof. R. H. Yapp, 293; Lice or Aphididae of Great Britain, The, F. V. Theobald. Vol. 3, 533; Life and its Romance, Prof. F. E. Weiss, 369; Pathology: and Physiology in Relation to Man, Lectures on, 257; Principles of, Prof. C. E. Owens, 257; Protection, The Scientific Principles of, H. Martin, 257
lants: of the Balkans, 6; Respiration of, Influence of Cold Waves on the, A. Hée, 503; The Pectic Substances of, M. H. Branfoot (M. H. Carré), 709
lasmatic Membrane, Electrical Excitation and the Possible Structure of the, Prof. H. H. Dixon and T. A. Bennet-Clark, 650
latinum Surface, Reaction on a, Donnelly and Hinshelwood, 556
latonist, A Modern, 979
leistocene Man in China, 973
lumage Coloration, Factors in, Drs. A. W. Greenwood and J. S. S. Blyth, 554
olarised Light: Reflection of, A. C. G. Beach, 373; Action of, on certain Photographic Plates prepared with Solutions of Colloidal Silver, A. Cotton, 861
olemonium, A Fertile Interspecific Hybrid in the Genus, C. H. Ostenfeld, 42
olish Broadcasting Organisation, Extension of the, 493
ollution and Bottom Faunas, R. E. Richardson, 428
olyalcohols, The Reducing Power of the, towards Alkaline Solutions of Potassium Iodomercurate, P. Fleury and J. Marque, 215
olychæta from the Relic Lake Palæostom (Western Caucasus) and the Rivers connected with it, N. Annenkova, 286
olycondensed Heteronuclear Systems, G. Charrier, 862
olyhalides (1), V. Caglioti, 79
olymorphinidæ, Japanese, Dr. J. A. Cushman; Prof. Y. Ozawa, 319
olynesia: and Melanesia: Researches in; an Account of Investigations in Samoa, Tonga, the Ellice Group, and the Hebrides in 1924, 1925. Dr. P. A. Buxton. Parts 5-7, relating to Human Diseases and Welfare, 910; Culture in, Miss Margaret Mead, 387
olyploid Species, A, Meurman, 318
olyploids and Polyploidy: C. D. Darlington, 62, 98
olytechnic, London, New Extension of the, 636
ond Snail, Growth of a, E. D. Crabb, 460
opulation Studies: Dr. C. Fenner, 425; Studies in South Africa, 708
ortland Island Museum, Plea for Exhibition Cases for the, Dr. Marie C. Stopes, 349
ortsmouth Municipal College, Work at the, 1004
ortuguese Mineral Waters, The Spectro-chemistry of, A. P. Forjas, 896
otassium: Ammonium, and Rubidium Sulphates, The Space Group and Symmetry of, Prof. A. Ogg, 394; Chloride, The Physiological Characteristics of, D. N. Prianishnikov and S. I. Inozemcev, 394
otato, The Food Value of the, for Albino Rats, A. Galamini, 674
otatoes, Preserved, J. Dunlop, 388
otential: Gradient and Atmospheric Pollution; the Influence of 'Summer Time', F. J. W. Whipple, 77; Temperature, Distribution of, in the first 25 Kilometres over the Northern Hemisphere, Dr. K. R. Ramanathan, 509
otentiometers, Alternating Current, Dr. C. V. Drysdale, 1001
ourridæ, The Plant Disease, and Calcium Carbonate, Gard, 780
ower: Resources of the World (Potential and Developed), H. Quigley, 573; Stations, Difficulties in Working, 922
raseodymium, Neodymium, and Samarium, Band Spectra of the Oxides of, Prof. G. Piccardi, 618
rehistoric: Archæology, South Africa's Contribution to, H. Balfour, 196, 268; Kitchen Midden in California, Birds of a, 632; Man in East Africa, E. J. Wayland, 279; Society of East Anglia, Summer Meeting of the, 464
Primary Tar, Cracking of a, from a Donetz Coal under Pressure in a Hydrogen Atmosphere, V. N. Ipatiev, A. D. Petrov, and I. Z. Ivanov, 286
Primates: The Developmental History of the, Prof. J. P. Hill, 850; The Subdivisions of the Order, Prof. G. Elliot Smith, 876
Primitive Beliefs in the North-East of Scotland, Rev. J. M. McPherson, 175
Primula kewensis, The Descendants of, and their Diversity of Form, E. Heinricher, 782
Probability, Theory of, late Dr. W. Burnside, 297
Productus and *Strophalosis* from the Branxton district, New Subgenera of, F. W. Booker, 359
Propionic Acid Bacteria, The, C. B. van Niel, 685
Propylbenzene, A New Method of Synthesis of, etc., L. Bert and M. Anglade, 862
Protein Metabolism in Plants, Miss M. E. Robinson, 159
Protisten und Thallophyten, Verteilung, Bestimmung und Vererbung des Geschlechts bei den, M. Hartmann, 262
Proton, Electron, and Helium Nucleus, The Relative Masses of the, E. E. Witmer, 180
Protophyta, Evolutionary Sequence among, Prof. Fritsch, 245
Protoplasm, The Colloid Chemistry of, Prof. L. V. Heilbrunn, 173
Protozoology: a Manual for Medical Men, J. G. Thomson and A. Robertson, 612
Proxima Centauri, Discovery of, at Johannesburg, 495
Prunella atrogularis and *P. montanella*, The Geographic Forms of, L. A. Portenko, 358
Psychiatry: Progress in, 222; Recent Advances in, Dr. H. Devine, 222
Psychology: Experimental Method in, F. C. Bartlett, 149; 341; in Education, Aspects of, Dr. C. W. Kimmins, 516; Industrial, edited by Dr. C. S. Myers, 545; Ninth International Congress of, 500; Social, Introduction to: Mind in Society, Dr. R. Mukerjee and Dr. N. Nath Sen-Gupta, 544; The A C B of, C. K. Ogden, 756
Puccinia graminis, Nuclear Association in the Æcium of, Dr. W. F. Hanna, 267
Pulmonary: Silicosis, Mechanism of, A. Policard, S. Doubrow, and M. Boucharlat, 826; Tuberculosis: A Text-Book of, for Students, R. C. Wingfield, 790
Pulverised Fuel in Electric Power Stations, R. A. Chattock, 707
Pyramidon, A New Product derived from, R. Charonnat and R. Delaby, 1007
Pyrethrum: Flowers, The Active Principles of, Gnadinger and Corl, 857; Insecticidal Constituents of, F. Tattersfield, R. P. Hobson and C. T. Gimingham, 555
Pyruvic Acid, Condensation of, with Formaldehyde in the Presence of Sulphuric Acid, V. Feofilaktov, 897

Quantique, Les méthodes nouvelles en analyse (mécanique quantique, mécanique ondulatoire), Dr. J. Pacotte, 176
Quantistic Electrodynamics, E. Fermi, 359
Quantitative Chemical Analysis by X-rays and its Application, Prof. G. Hevesy, 841
Quantum Theory: and Special Relativity, Dr. M. S. Vallarta, 336; of the Absorption of Light, The, Prof. J. Frenkel, 758
Quartz: Crystal Oscillators, High Frequency, F. R. Lack, 821; -felspar Rock, On a partially, and on Glomerogranular Texture, Dr. L. Hawkes, 76; Oscillating Piezo-electric, The Vibrations along the Optic Axis in an, E. P. Tawil, 358; Tuning Fork in a High Vacuum, Preliminary Study of a, Holweck and Lejay, 114
Queensland Fruits and Vegetables, Pests and Diseases of, R. Veitch and J. H. Simmons, 887

'R 101', Prof. R. V. Southwell, 915
Radcliffe Observatory, The, 849
Radiation Hypothesis of Chemical Reaction, The, W. Ure and R. C. Tolman, 35
Radioactive: Disintegration, The Temperature Coefficient of, O. K. Rice, 603; Recoil Ions of High Mobility, Existence of, L. L. Loeb and L. B. Loeb, 288

Radioactivity, Measurement of, H. Neufeldt, 857
Radio : Communication in the British Navy, 967 ; Echoes, Long Delayed, Principal Pedersen, 164 ; Signals, Magnetic Storms and, Miss I. J. Wymore, 109 ; Stations : New, in Spain, 736 ; Short Wave, in New Jersey, 241 ; Telephone Sets for Light Aeroplanes, 104 ; Time Signals, A. R. Hinks, 821
Radium : and Cancer, 815 ; Commission : acceptance of the chairmanship by Lord Lee of Fareham, 276 ; Composition of the, 316 ; Prof. S. Russ appointed scientific secretary of the, 550 ; Treatment of Cancer, S. Cade, 836 ; Trust, The National, and the Purchase of Radium, 316 ; *D*, J. Petrová, 425 ; Emanation Therapy, Physical Foundations for, S. Meyer, 827 ; Radiation, The Colouring by, of Rock-salt Crystals, etc., H. Schober, 782 ; Radiations, Penetrating, Chemical Actions of (18), A. Kailan, 746
Radon in Quartz Capillary Tubes, The Disappearance of, during Electrodeless Discharge, H. Pettersson, 1008
Rain : Shortage of, over the British Isles, 30 ; The Areas covered by Intense and Widespread Falls of, Dr. J. Glasspoole, 996
Rainfall : Attempts to Induce, C. W. Jeffries, 482 ; Forests and, J. W. Nicholson, 820 ; March, of North-West India and Agra Upper Winds in December-January, M. V. Unakar, 618 ; of September, The, and to the end of September, 663 ; over Great Britain—January to June, 207
Rainhill Locomotive Trials, Exhibits at the Science Museum illustrating the, 66
Raman : Effect : S. L. Ziemecki and K. Narkiewicz-Jodko, 890 ; and Electrolytic Dissociation, I. Ramakrishna Rao, 762 ; for X-rays, The, Prof. D. Coster, I. Nitta, and W. J. Thijssen, 230 ; D. P. Mitchell, 246 ; from Powdered Crystals, A. C. Menzies, 511 ; Prof. R. Bär, 692 ; in Carbon : Dioxide, Prof. P. N. Ghosh and P. C. Mahanti, 92 ; Disulphide, The, A. S. Gavesan and S. Venkateswaran, 57 ; in Diatomic Gases, The, F. Rasetti, 216 ; in Gases and Liquids, Prof. P. N. Ghosh and P. C. Mahanti, 230 ; Studies on the, A. Dadieu and K. W. F. Kohlrausch (5), 971 ; The Quantum Theory of the, E. Amaldi, 359 ; Lines, Influence of Temperature on, Y. Fujioka, 11 ; Spectra : and Ultra-Violet Absorption, A relation between, A. Langseth, 92 ; in Atmospheres surrounding Metallic Arcs, B. Venkatesachar and L. Sibaiya, 838 ; of Gypsum, R. T. Dillon and R. G. Dickinson, 898 ; of some Hydrogen Compounds, Comparative Study of the, Daure, 77 ; of Sulphates, S. K. Mukerjee and P. N. S. Gupta, 354 ; Spectrum and Fluorescence of Benzol, C. V. Shapiro, 372
Ramsay Memorial Fellowships, awards of, 165
Ranunculus, Studies on, Marsden-Jones and Turrill, 928
Rapid Approximate Calculation, R. d'E. Atkinson, 94
Rare : Earth Salts, A New Type of, G. A. Barbieri, 359 ; Earths, The Paramagnetic Properties of the, B. Cabrera and A. Duperier, 215 ; Metals, Determination and Separation of, from other Metals, L. Moser and W. Reif (16), 781 ; L. Moser and W. Blaustein (17), 781
Rassenkreise, Das Prinzip geographischer, und das Problem der Artbildung, Dr. B. Rensch, 753
Rat, Variations of the Rest Metabolism of the, in relation to the Sex Cycle, A. C. Fraser and B. P. Wiesner, 826
Rats, On the Geotropic Response in Young, G. Pincus and W. J. Crozier, 603
Reading University, J. R. Matthews appointed professor of botany, 778
Rearing Experiments with Starfish and Obstetric Toads, Prof. E. W. MacBride, 727
Red : Cyanogen Bands, Vibrational Quantum Analysis of, R. K. Asundi and J. W. Ryde, 57 ; Sea, Certain Characteristics of the, with regard to the Nitrogen Cycle, G. Bini, 674
Reflectivity of Woodland, Fields and Suburbs between London and St. Albans, Dr. L. F. Richardson, 861
Reflex Activity, The Earliest Exhibition of, O. R. Langworthy, 554
Refractive Indices, A Photographic Method of Measuring, Prof. T. M. Lowry and C. B. Allsopp, 825
Reinforced Concrete Caisson, Righting a Heavy, F. W. Skinner, 208
Relativity : Special, Quantum Theory and, Dr. M. S. Vallarta, 336 ; The Coefficients of, Prof. S. R. Cook, 247
Reptiles, Placentation in (1), H. C. Weekes, 287
Reserve Fats in Seeds during Germination, The Transformations and Saponification of the, J. Lemarchands, 503
Resolving-power Tests on Microscope Objectives used with Ultra-violet Radiation, B. K. Johnson, 861
Resonators, The Dynamical Theory of, E. T. Hanson, 933
Retarded Echoes [in Wireless Telephony], Prof. C. Størmer, 503

REVIEWS AND OUR BOOKSHELF.

Agriculture, Forestry, and Horticulture :

Barrett (O. W.), The Tropical Crops : or Popular Treatment of the Practice of Agriculture in Tropical Regions, with discussion of Cropping Systems and Methods of Growing the leading Products, 440
Cox (J. F.), and C. R. Magee, Alfalfa, 369
Hall (Sir A. Daniel), Fertilisers and Manures. Third Edition, 530 ; The Book of the Tulip, 530
Hammer (Prof. B. W.), Dairy Bacteriology, 685
Hoare (A. H.), The English Grass Orchard, and the Principles of Fruit Growing, 529
Howard (A. and Gabrielle L. C.), The Application of Science to Crop Production : an Experiment carried out at the Institute of Plant Industry, Indore, 974
Landwirtschaft, Handbuch der. Herausgegeben von F. Aereboe, J. Hansen und T. Roemer. Fünf Bände. Lief. 8, Band 1. Lief. 9, Band 2. Lief. 10, Band 4. Lief. 11, Band 2 (Schluss) ; Band 3, 569
O'Brien (Prof. G.), Agricultural Economics, 531
Orr (Dr. J. B.), with the assistance of Helen Scherbatoff, Minerals in Pastures and their relation to Animal Nutrition, 437
Stapledon (Prof. R. G.), A Tour in Australia and New Zealand : Grass Land and other studies, 530
Stebbing (Prof. E. P.), The Forestry Question in Great Britain, 476

Anthropology and Archæology :

Allier (R.), translated by F. Rothwell, The Mind of the Savage, 910
Astley (Rev. H. J. D.), Biblical Anthropology compared with and illustrated by the Folk-lore of Europe and the Customs of Primitive Peoples, 223
Besson (M.), Le totémisme, 686
Bleek (Miss D. F.), Comparative Vocabularies of Bushman Languages, 224
Boas (Prof. F.), Anthropology and Modern Life, 754 ; Materials for the Study of Inheritance in Man, 532
British School at Athens, Annual of the, No. 28, Session 1926–1927, 88
Butt-Thompson (Capt. F. W.), West African Secret Societies : their Organisations, Officials, and Teaching, 872
Dawson (W. R.), The Custom of Couvade, 790
Driberg (J. H.), The Savage as he really is, 720
Geddes (Dr. A.), Au pays de Tagore : la civilisation rurale du Bengale occidental et ses facteurs géographiques, 532
Hellenic Studies, The Journal of. Vol. 49. Part 1, 121
Kittredge (G. L.), Witchcraft in Old and New England, 521
Lancaster Witches, The Trial of the, A.D. MDCXII. Edited with an Introduction by G. B. Harrison, 678
Malinowski (Prof. B.), The Sexual Life of Savages, 870
McPherson (Rev. J. M.), Primitive Beliefs in the North-East of Scotland, 175
Murray (Miss M. A.), Excavations in Malta. Part 1. With a Chapter by Miss G. Caton-Thompson. Part 2. With a Chapter by Miss G. Caton-Thompson. Part 3. With a Chapter by C. A. Mitchell and T. J. Ward, 719

Nanjundayya (the late H. V.), and Rao Bahadur L. K. Ananthakrishna Iyer, The Mysore Tribes and Castes. Vol. 2, 788
Schütte (Dr. G.), Our Forefathers, the Gothonic Nations, 531
Seabrook (W. B.), The Magic Island, 521
Stein (Sir Aurel), On Alexander's Track to the Indus, 531
Tabouis (G. R.), Translated by M. R. Dobie, The Private Life of Tutankhamen. Love, Religion and Politics at the Court of an Egyptian King, 872
Woolley (C. L.), The Excavations at Ur and the Hebrew Records, 223

Biology:

Allan (Dr. H. H.), New Zealand Trees and Shrubs: and how to Identify them, 717
Allorge (P.), and others, Contribution à l'étude du peuplement des hautes montagnes, 532
Anthony (H. E.), Field Book of North American Mammals: Descriptions of every Mammal known north of the Rio Grande, together with Brief Accounts of Habits, Geographical Ranges, etc., 836
Aron (Prof. M.), Vie et réproduction: notions actuelles sur les problèmes généraux de la biologie animale, 534
Astley (A.), From a Bird-Lover's Diary, 573
Bateson (William): Edited, with an Introduction, by Beatrice Bateson, Letters from the Steppe: written in the years 1886–1887, 533; Scientific Papers of, Edited by Prof. R. C. Punnett. 2 Vols., 171
Baylis (Dr. H. A.), A Manual of Helminthology; Medical and Veterinary, 261
Beebe (Dr. W.), Beneath Tropic Seas: a Record of Diving among the Coral Reefs of Haiti, 476
Biologie: Jahresbericht über die wissenschaftliche, zugleich Bibliographisches Jahresregister der Berichte über die wissenschaftliche Biologie, Herausgegeben von Prof. T. Péterfi. Band 1, 262; Wissenschaftlichen, Methodik der, Herausgegeben von T. Péterfi, Bände 1 and 2, 223

k Ice Dam, Bursting of the, 316
alling, Optical, in Germany, 959
on : The Catalysis of the Solution of, in Hydrofluoric Acid and the Influence of Tempering, C. Bedel, 862 ; The Oxidisability of : and its Solubility in Hydrofluoric Acid, C. Bedel, 358 ; as a Function of its State of Division, A. Sanfourche, 781
ate, Physikalische Chemie der, Dr. W. Eitel, 535
Silkworms, Vaccination of, Dr. D. Carbone, 33
Silver : in Water, Dissolution of, Křepelka and Toul, 72 ; -zinc Alloys, The Internal Transformations of the, A. Roux and J. Cournot, 41
Sinanthropus Pekinensis, Prof. Davidson Black, 245
Sinnesorgane : Die stiftführenden, Morphologie und Physiologie der chordotonalen und der tympanalen Sinnesapparate der Insekten, Prof. F. Eggers, 532
Size of Living Things, The, Prof. J. S. Huxley, 818
Slash in Chir Pine Forests in the North-West Himalaya, Treatment of, J. E. C. Turner, 463
Small-pox, etc., " Flocculation Test " for, W. J. Burgess, J. Craigie, and W. J. Tulloch, 703
Smithsonian Institution, Explorations and Field Work of the, in 1928, 458
Snails, Pond, Polyvitelliny in, E. D. and R. M. Crabb, 318
Snake-like Caterpillars, Recent Observations on, Prof. E. B. Poulton, 933
Snakes and Termites—a New Example of Symbiosis, Dr. F. Kopstein, 632
Soap Films : a Study of Molecular Individuality, A. S. C. Lawrence, 540
Social : Ethics, Darwinism and, Bishop of Exeter, 217 ; Psychology : the Psychology of Political Domination, Prof. C. Murchison, 476
Society : An Introduction to the Study of, an outline of Primary Factors and Fundamental Institutions, Prof. F. H. Hankins, 645
Sociology ? What is, 645
Sodium : and Chromium, The Emission of Anode Rays of, A. Poirot, 358 ; A Qualitative Reagent for, E. R. Caley, 389 ; Potassium, Calcium, and Magnesium in Muscular Fluid and in its Ultra-filtrate, G. Quagliariello, 638 ; Solid, and Potassium, The Densities of, E. Rinck, 252
Softwood Timber, Commercial, The threatened Shortage of, 848
Soil-testing Outfit, Simple, British Drug Houses, Ltd., 425
Soils and Fruit of Wisbech, Wright and Ward, 739
Solar : Activity : 69, 888 ; Curve of, from 1877 to 1928, L. Taffara, 278 ; Recent, 737 ; Eclipse, The Total, at Iloilo, on May 9, Dr. R. L. Waterfield, 177 ; Images at the Focus of a Telescope, A partial case of Diffraction of the, M. Hamy, 114
Solutions, Viscosity of, G. Jones and M. Dole, 857
Solvay, Institut International de Physique, Électrons et photons : rapports et discussions du cinquième Conseil de Physique tenu à Bruxelles du 24 au 29 octobre 1927 sous les auspices de l'Institut International de Physique Solvay, 369
Sorby Research Fellowship, appointment to the, of Dr. W. H. George, 39
Sound : -films, etc., Experiments with, J. B. Taylor, 852 ; Intensity, The Absolute Measurement of, F. D. Smith, 113 ; Speech, and Hearing, Dr. W. H. George, 365 ; Test Records, 741 ; Vibrations, Z. Carriére, 498 ; Waves, Low Frequency, and the Upper Atmosphere, E. H. Gowan, 452
Sounding Dust Tube, New Phenomena in a, E. J. Irons, 914 ; Prof. E. N. da C. Andrade and S. K. Lewer, 724
South : Africa : Palæobotanical Evidence for the Age of the Late Palæozoic Glaciation in, Dr. J. Walton and Dr. H. Dighton Thomas, 614 ; Problem of the Pre-European Miners and Smelters of, Dr. P. A. Wagner, 493 ; The Advancement of Science in, 117 ; The Stone Age Culture of, C. van Riet Lowe and A. J. H. Goodwin, 550 ; Union of, The Demographic Position in the, Dr. J. E. Holloway, 708 ; African : Branchiopoda, Dr. Barnard, 738 ; Sheep, The Shearing of, Prof. A. F. Barker, 816 ; Africa's Contribution to Prehistoric Archæology, H. Balfour, 196, 268
Space : Curvature of, Dr. E. P. Hubble, 158 ; The Life of, M. Maeterlinck. Translated by B. Miall, 872 ; -time, Curvature Radius of, New Determination of the, Dr. L. Silberstein, 179
Spark Discharge, The Mechanism of, L. J. Neuman, 216
Species : etc., Origin of, The Early Chinese and the, Tze Tuan Chen, 276 ; Problem, The, in the Light of Genetics, J. B. S. Haldane, 514

Specific : Heat of a Material in Powder Form, Apparatus for Determining the, J. H. Awbery and Dr. E. Griffiths, 1006 ; Heats at Low Temperatures, S. Mitsukuri and N. Hara, 34
Spectrometer for the Infra-red, A Recording, P. Lambert and J. Lecomte, 358
Spectrometers, Diffraction in, Prof. A. G. Shenstone, 634
Spectroscopy of the Extreme Ultra-Violet, The, Prof. T. Lyman. Second edition, 756
Spectrum of a Spark in relation to the Concentration of the Element, Length of the Lines in the, A. Occhialini, 79
Speech and Hearing, Dr. H. Fletcher, 365
Speed Record, A New Seaplane, Squadron-Leader Orlebar, 457
Sphodromantis bioculata, Growth Measurements in, Prof. H. Przibram (4), 782
Spider, Non-Nucleated Blatospheres of a, Dr. E. Warren, 1000
Spinels of the Type $Me_2''Me^{IV}O_4$, G. Natta and L. Passerini, 79
Spinning : Electron, The Second-order Wave Equations of the, G. Temple, 41 ; Target X-ray Generator, A, Dr. A. Müller, 128
Spinoza, The Correspondence of, translated and edited with Introduction and Annotations by Prof. A. Wolf, 787
Spirit Hunting in the South Seas, Prof. B. Malinowski, 923
Spitsbergen Papers. Vol. 2, 533
Splitting of Systematic Groups, the, Dr. Handlirsch, 996
Sponge : Cells, Behaviour of, M. W. de Laubenfels, 666 ; Hexactinellid, Development of a, Y. Okada, 70
Sponges, Deep-water, M. Burton, 279
Squid, A New, S. S. Berry, 667
Standard Cells, Prof. G. A. Hulett and W. S. Niederhauser, 598
Star-cloud in Scutum, The, C. J. Krieger, 854
Stark Effect in Stellar Spectra, Dr. O. Struve, 278
Starlight, Prof. H. N. Russell, 386
Starry Sky, How to enjoy the, M. Woodward, 407
Stars : Double : Prof. Aitken's, Prof. Aitken, 278 ; Measurements of, G. Armellini, 862 ; Early Type, Variation of the Calcium *K* Line with Distance in, Dr. J. H. Oort, 386
State Scientific Service, A, 325
Statistica, Contributi del Laboratorio di. Serie Prima, 873
Statistics and Biological Research : Dr. E. S. Pearson, 615 ; Dr. R. A. Fisher, 266 ; Prof. Karl Pearson, 183 ; " Student ", 93
Steam : and other Engines, J. Duncan. Revised and enlarged edition, 834 ; Engine in America, The First, L. F. Loree, 702 ; Tables, New, Prof. H. L. Callendar, 35 ; Turbine Progress, Hon. Sir Charles Parsons, 389 ; Turbines, Eng. Lieut.-Comdr. T. M. Naylor, 539
Steelmaking, Practical, W. Lister, 401
Steels, Structural, in High Elastic Limit, J. A. Jones, 741
Stellar : Parallaxes, Dynamic, A Catalogue of, Prof. H. N. Russell and Charlotte E. Moore, 772 ; Spectroscopy at Dominion Observatory, Victoria, R. N. van Arnam ; W. E. Harper, 888
Stenetrium from Western Australia, Some New Species of, G. E. Nicholls, 467
Steppe : Letters from the, written in the Years 1886–1887, W. Bateson. Edited, with an Introduction, by Beatrice Bateson, 533
Sterigmatocystis nigra : Relation between the Nature of the Glucides of, and that of the Sugars supplied to it, F. Obaton, 896 ; The Physiological Characters presented by, when lacking Zinc and Iron, M. Molliard, 745
Sterols : The Photochemical Activity of various, and the Nature of their Action, L. Hugounenq and E. Couture, 252 ; The Photographic Effect produced by the, after Exposure to Ultra-violet Light, J. Cluzet and Kofman, 252
Strawberries, The Genetics of, Heterosis, F. Chodat, 215
Streams, Fauna of, E. Percival and H. Whitehead, 633
Street Lighting Engineer, The Duties of the, S. B. Langlands, 735
Stress produced in a Semi-infinite Solid by Pressure o Part of the Boundary, Prof. A. E. H. Love, 40
Stresses : in the Neighbourhood of a Circular Hole in Strip under Tension, The, R. J. C. Howland, 932 Structural, Profs. F. B. Seely and R. V. James, 1001
Strontium : The Crystal Structure of, A. J. King, 288 The Physiological Action of, M. Comel, 115
Strychnine and Brucine, A Link between, H. Leuchs, 82
Subject Index to Periodicals, The, 1927, 122
Submarine Canyons, The Earthquake south of Newfound land and, Prof. J. W. Gregory, 945
Sugar : Cane, Synthesis of, Pictet and Vogel, 320 ; group Synthetic Experiments in the, N. Fröschl, J. Zellne and H. Zak (1), 1007
Sugars : A New Transition from, to the Furane group E. Votoček and S. Malachta, 898 ; The Constitutio of, Prof. W. N. Haworth, 291
Sulphide Colours on Metallic Copper, Dr. F. H. Constable 41
Sulphur : Chlorides of, Prof. T. M. Lowry and G. Jessop 389 ; in Dithionates, The Valence of, R. E. Winge and D. M. Yost, 467 ; Monoxide, Prof. V. Henri an F. Wolff, 160 ; treatment of a Soil and its Effect o Wheat Yield, Some Experiments dealing with, Mar D. Glynne, 359
Sumeria and Oceania, Dr. P. Rivet, 999
Summer of 1929, The, and the Solar Variations, H. Mémery 745
Sun : The, Dr. C. G. Abbot. Revised edition, 331 ; Th Cult of the, Mrs. Zelia Nuttall, 822 ; The Eclipse o the, of Nov. 1, 1929, at Geneva, E. Rod and G. Tiercy 43 ; Total Eclipse of the, Observations of the, at Alo Star, Kedah, on May 9, Dr. J. Jackson, 90
Sundial, New, Gift of a, to the Royal Botanical Gardens Kew, by Prof. C. V. Boys, 965
Sunlight and Fresh Air, Effect of, on Animals at the Zoo Dr. Vevers, 242
Sunspot, Naked-eye, 998
Sunspots : and Pressure, M. V. Unakar, 11 ; Recent, 631
Sunrays and Health, R. Millar, in collaboration with D E. E. Free, 873
Sunrise on the Moon, Kinematographic Record of, R. I Arnott, E. G. F. Arnott, A. L. Bennett, and Prof. J. C Stewart, 56
Sun's Atmosphere, Turbulence in the, W. H. McCrea, 442
S.U.P. 36, Action and Uses of, 885
Superconductivity in a Compound, Prof. W. Meissner 929
Super-cooled Water, Dr. L. Hawkes, 225
Superficial Solutions and Molecular Films, F. Emir, 431
Superhardening Hardened Steel by Magnetic Means, E. G Herbert, 672
' Supersonic ' Radiation in Liquids, An Intensity Gaug for, W. T. Richards, 288
Superstition, Sir Robert Armstrong-Jones, 769
Surface : Coatings on Water and Molecular Dimensions A. Marcelin, 431 ; Forces and Chemical Equilibrium Prof. H. Freundlich, 957
Surgery, Modern, Influence of other Sciences upon th Practice of, Prof. A. H. Burgess, 154
Surveyors and Map-Makers of the Sixteenth, Seventeenth and Eighteenth Centuries and their Work, Som Notable, Sir Herbert George Fordham, 540
Surveys, National, Brigadier E. M. Jack, 147, 487
Swan, Sir Joseph Wilson, F.R.S. A Memoir by M. E. and K. R. S., 567
Sweden, Afforestation of Peat Lands in, C. Malmström 111
Swedish Rivers, Flow of, G. Slettenmark, 634
Swimming Bath Water, Purification of, 819
Sydney Harbour, A Possible Relict Fauna in, T. Iredale 596
Syllis (*Haplosyllis*) *spongicola*, The Sexual Stolons of, Gravier and J. L. Dantan, 358
Symons gold medal of the Royal Meteorological Society award of the, to Dr. G. C. Simpson, 664
Syncaridan, A New, from the West Coast of Tasmani G. E. Nicholls, 825
Syntheses and Protheses in Bone, in Metal uncovered covered with Rubber, Robineau and Contreomulin 115

es annuelles de constantes et données numériques de chimie, de physique, de biologie et de technologie. Vol. 6 : Années 1923–1924, 51

Problems of Geochemistry.

IN his recent lecture at the Royal Institution, parts of which are reproduced in this issue of NATURE, Prof. V. M. Goldschmidt presented a brilliant summary of the broader problems of geochemistry and of some of the conclusions that have been reached in the effort to solve those problems. His view of the concentric architecture of the earth, and in particular of the 'eclogite' and 'sulphide-oxide' shells, is one that has received much more attention on the Continent than in the English-speaking countries. In Britain and America the substratum between the crust and the core is more generally supposed to be of the composition of peridotite. More important, however, than a reminder of such differences of opinion, is Prof. Goldschmidt's summary of the principles which enable geochemistry to enter into partnership with geophysics in the difficult investigation of our planet's hidden depths. The laws that govern the vertical distribution of the chemical elements, their partition between the different shells of the earth, are gradually being recognised, and their integrated effects can be tested by an appeal to the zones that are accessible to observation. Conversely, the composition of these zones affords a valuable series of clues as to the nature of the deeper layers. In particular, the abundance of iron among the predominating lithophile elements of the crustal rocks gives a clear indication that iron must be the chief constituent of the core. Confirmatory evidence is forthcoming from the samples of other cosmic bodies which, as meteorites, are captured by the earth. They, too, have their nickel-iron phases and their silicate phases, in close analogy with the composition assigned on

technological grounds to the principal parts of the earth.

The analogy is, unfortunately, not a safe one to follow too far, since many meteorites bear distinct signs of having had a volcanic origin, and none that has yet been discovered represents the mineral assemblage of the high-pressure or 'eclogite' facies of silicate rocks. Nevertheless, meteorites provide precious data bearing on the natural association of elements, and these, together with spectroscopic evidence of the composition of stellar atmospheres, are found to be closely in accordance with the associations characteristic of our own terrestrial materials.

Less speculative, but of absorbing interest and economic importance, is Prof. Goldschmidt's discussion of the concentration of the rarer elements in the residual liquors of magmas. Corresponding with his deduction that two very different types of elements would be expected to remain in the final liquors, we find in pegmatites minerals of elements with very small atomic sizes (for example, lithium, boron, and fluorine) associated with others containing the large-size elements (for example, zirconium, thorium, uranium, niobium, and tantalum). It has frequently been asserted that the heavy radioactive elements might be expected to be concentrated in the deeper and heavier levels of the earth's interior. The geochemistry of both igneous rocks and meteorites affords no support to this superficial view, but indicates, on the contrary, that these markedly lithophile elements, ultimately sorted out in virtue of their atomic sizes, should be steadily concentrated in the uppermost levels of the earth's crust, the effect being cumulative with each successive igneous cycle.

Geochemistry has before it a broad and attractive field to cultivate. Not only the *vertical* distribution of elements, but also their *horizontal* distribution needs to be correlated with geological structure and geological history, and finally there remains for much further study the geochemistry of the secondary geological processes such as weathering, sedimentation, and metamorphism. Prof. Goldschmidt, more than any other single investigator, has developed the principles and methods most likely to yield a rich harvest. They deserve particular attention in Great Britain, where geochemistry has been somewhat neglected, for, as his stimulating lecture clearly reveals, their application to problems of petrogenesis and ore-deposition, as well as to the material aspects of geological processes in general, is already achieving a series of encouraging results.

Low-Temperature Carbonisation.

The Technology of Low Temperature Carbonizatio
By Frank M. Gentry. Pp. xvii + 399. (London Baillière, Tindall and Cox, 1928.) 34*s*. net.

WHEN coal is burned in open grates, an indeed, in many industrial furnaces, large proportion of the volatile contents of th coal escapes into the atmosphere unburnt, or bu partially burnt, in the form of oily vapours an particles of soot. The resulting pollution of th atmosphere, particularly in large residential centre is a serious civic problem, resulting in much defac ment of buildings and impoverishment of health.

With, possibly, one or two exceptions, our smok abatement laws are framed to restrict the discharg of smoke from industrial stacks as distinct fro domestic chimneys. In most large cities, howeve the smoke nuisance arises mainly because bitumino coal is burned in domestic grates.

The discharge of smoke from industrial stacks much less to-day than it was twenty years ag because the scientific investigation of combusti processes has led to a great improvement in th design and operation of furnaces. With few e ceptions, the discharge of smoke from a facto stack is unpardonable and indicates a lack scientific control in the furnace room.

The increasing use of gas and electricity, and th correspondingly diminished amount of bitumino coal that is burnt in domestic fireplaces, is reflecte in lower concentrations of smoke in the atmosphe above large cities. There still remains, howeve much room for, and indeed much need of, im provement, and this improvement can be broug about mainly by preventing the discharge of smo from domestic chimneys. To some extent th will be accomplished automatically by the furth development of gas and electric heating. It unlikely, however, that coal as a domestic fu will be completely displaced by these alternativ for many years to come.

It is possible to prevent this smoke formati by removing the volatile constituents from t coal before it is burnt in the grate. This is alrea done in the gasworks, but the resulting coke difficult to ignite and cannot readily be burnt domestic grates. If the volatile constituents cou be removed from the coal and a residue be obtain which would burn freely and give out plenty heat, and which could be obtained at a pri comparable with that of coal and, at the same tim yield a profit on the undertaking, the use of th residual material would, conceivably, becor

neral and the discharge of smoke from domestic mneys would become a thing of the past.

This is one motive for the investigation of the -temperature carbonisation of coal. There is ther: To the chemical engineer, coal is some-ng more than a fuel; it is a complex raw terial, from which, by suitable means and with appropriate plant, many valuable liquid and seous products can be obtained, leaving a solid idue which is still a valuable combustible. These ducts may be used in various ways—for example, fuel for internal combustion engines, as lubri-nts, as fertilisers, or as starting materials for the nufacture of a wide range of organic compounds. To separate a volatile fuel oil from coal and burn in an internal combustion engine is to use it re conveniently and more efficiently, so that form value is increased. To use a separated nstituent as a raw material in chemical industry better than burning it, however efficiently, along h the parent coal.

The problem before the chemical engineer, there-e, is the development of a process by which the l potential chemical value of the coal can be lised most completely, not simply by burning coal with the highest efficiency under a boiler, even in powdered form in an internal combustion gine, if that were possible, but by obtaining its ious components in the forms in which they l possess the highest industrial value. The mediate problem of low-temperature carbonisa-n is the design of a retort in which the preliminary aration can be carried out efficiently and nomically.

To some extent this ideal has been realised in the product recovery coke oven and the gas retort; ng to the high temperature at which these cesses operate, however, a large proportion of volatile constituents of the coal is converted gas. By carrying out the destructive distillation he coal at lower temperatures, it is possible to ain a smaller proportion of gas and a corre-ndingly greater quantity of oils. The solid bonaceous residue, unlike the products of the e oven and the gas retort, is very reactive, ites readily, and burns on a domestic grate freely without smoke. Its superior reactivity may ke it suitable for special purposes and ultimately ance its market value. Low-temperature, or imary', tar differs both chemically and physic-from the high-temperature tar from gas rts or coke ovens. A special technique has yet e worked out for its subsequent treatment and luation.

Most of the earlier work on low-temperature carbonisation was carried out in Great Britain and in Germany; a considerable amount of work has also been done in America. Some hundreds of processes have been worked out in the laboratory; many of these have been worked on a semi-technical or technical scale, and a few of them are now being operated tentatively as large industrial units.

It is difficult, at present, to estimate the economic possibilities of low-temperature carbonisation. An immense amount of work has been done upon the design of a suitable retort, particularly in relation to the materials of construction, the movement of the charge through the retort, and the economical utilisation of the heating medium. Economic success will also depend upon the market value of the products. This value cannot yet be fully realised, for the subsequent separation and utilisation of the somewhat peculiar products still remain to be worked out. It would seem that ultimate success depends upon reducing the cost of carbonisation below a few shillings per ton, discovering new uses for primary tar and gases so as to make them more valuable than the present by-product tar and gas from high-temperature processes, or finding a use for the solid residue which will enable it to bring in a revenue equivalent to the original value of the coal. It is possible that, when satisfactory processes are developed, they may be encouraged by a Government subsidy in the interests of public health and civic well-being.

Mr. Gentry has done a great service to all who are interested in the more effective utilisation of coal by writing a most excellent and comprehensive critical account of the work that has already been done in this field. He has produced a book of nearly four hundred pages which is packed with trustworthy information and sound criticism. After a preliminary chapter dealing with the fundamental principles involved in the heating and destructive distillation of coal, separate chapters are devoted to the production and properties of the various products of low-temperature carbonisation: gas, tar, coke, and nitrogenous and other by-products. In each chapter, the various factors which affect the yield and character of the particular product, such as the character of the coal, the rate of heating, the character of the gaseous atmosphere and the secondary decomposition of primary products, are clearly discussed. Some fifty pages are then devoted to a detailed description of a number of typical plants and processes, the characteristic features of each being well described. After a valuable chapter dealing with the design and operation of

different retorts, the behaviour of various construction materials under low-temperature carbonisation conditions and the transfer of heat through these materials, the book closes with a thoughtful and stimulating chapter in which the economics of low-temperature carbonisation are carefully considered. Such important matters as the yields of the different products and the resulting revenue, capital and operating costs, actual and potential markets for the different products, and the influence of plant location and fuel supplies, are discussed fully.

This is the best up-to-date account of the subject that is known to the reviewer. The immense amount of information is handled in a masterly manner; it has been well chosen; it is arranged logically and clearly; the conclusions are well found and clearly presented. The book is well illustrated. Its value is enhanced by more than four hundred references to original papers.

The book can be commended confidently to all who need a clear and authoritative account, from the theoretical or practical aspect, of the low-temperature carbonisation of coal. W. E. G.

Mathematical Notation through the Centuries.

A History of Mathematical Notations. By Prof. Florian Cajori. Vol. 1: *Notations in Elementary Mathematics.* Pp. xvi + 451. (Chicago and London: The Open Court Publishing Co., 1928.) 25*s.* net.

THE work before us constitutes an important contribution to the history of mathematics. The development of mathematical notation is a fascinating subject in itself; but, the literature being so vast and scattered, it is difficult, without such a guide as is here presented, to study it effectively; in fact, apart from such a vademecum, it would be necessary to spend years (almost) in studying the original documents in the great libraries. Now, however, thanks to the labours of Prof. Cajori, which must have been colossal, we are given a conspectus of the whole subject so far as elementary mathematics are concerned.

The work was originally intended to be brought out in one volume, but the author, on second thoughts, decided (wisely, as we think) to divide it into two volumes, and to confine the first of the two to the history of symbols in elementary mathematics, "since such a volume would appeal to a wider constituency of readers than would be the case with the part on symbols in higher mathematics". As it is, the volume before us is as larg as can be conveniently handled. It contains however, everything which a student of the subjec is likely to require. Besides many hundreds c references to the literature, it gives extracts fro all the known books, from the invention of printin onwards, which are significant from the point c view of notation, more than a hundred facsimile of printed pages, and reproductions of simila matter from MSS. showing still earlier stages in th development of various signs.

After a page of introduction, Part II. deal with numeral systems and symbols (Babylonian Egyptian, Phœnician and Syrian, Hebrew, Cretan Greek, early Arabian, Roman, Peruvian, Azte Maya, Japanese, Chinese, and finally the Hindu Arabic numerals). Part III. is devoted to th symbols used in arithmetic and elementary algebra and Part IV. to those belonging to elementar geometry. Part III. is in two sections. Th first (A) describes the symbols, in chronologica order as it were, under individual authors, Greek Hindu, Arabic, Byzantine, and finally medieva and modern, the latter arranged according t periods and countries. This section contains th facsimiles of passages from MSS. and of printe pages from the earliest printed arithmetic (th Treviso Arithmetic, 1478) onwards. Among ther are specimens from MSS. of Nicole Oresme (14th c. Regiomontanus and Nicolas Chuquet (15th c.), an printed pages of works by Paciuoli, Cardano Tartaglia, Bombelli, Widman, Schreiber (Gram mateus), Christoff Rudolff, Stifel, Stevin an Girard, Nuñez, Recorde, Leonard and Thoma Digges, Peletier, Vieta, Harriot, Hérigone, Descartes Barrow, Rahn, Wallis. There is also an elaborat account of the symbols (some 150 in number) use by William Oughtred, whose influence in thi regard was second to none; after him the importan names are those of Barrow, Wallis, and Leibniz.

In reading Section A of Part III. the reader i in danger of not seeing the wood for the trees, s bewildering is the variety of the symbols used b the several authors; but here Section B come to our assistance. In this, Prof. Cajori gives wha he calls a "Topical Survey of the Use of Notations" The object of the history is, as he says, to give no only the first appearance of a symbol and its origi (where possible), but also to indicate the competi tion encountered and the spread of the symbol among writers in different countries, the rise c certain symbols, their day of popularity, thei eventual decline, and so on. It is this specia survey in Section B which is perhaps the mos

luable portion of the work, for in it the author esents " a mirror of past and present conditions mathematics ", in the belief that " the successes d failures of the past will contribute to a more eedy solution of the notation problems of the esent time ".

Among interesting details in the volume we may te the following. It is curious to find that the nification of numbers by knots in strings appears Peru under the Incas and also in the earliest inese system, that the Maya of Central America d a numeral system which was vigesimal except the second step, where 18 took the place of 20, d that the Maya system exhibited the principle ' place value ' and the use of a symbol for zero out the beginning of the Christian era, and erefore centuries before the Hindus began to e their symbol for zero.

It appears that the + and − signs used in print the first time by Widman (1489) are found in S. of 1481 and 1486, now at Dresden, which re studied and annotated by Widman. The n = for equality, which we owe to Robert corde (" The Whetstone of Witte ", 1557), ms to have been used independently about the ne time (between, say, 1551 and 1568) by a thematician at Bologna. The signs > and < ' greater than ' and ' less than ' are due to rriot (1631); they ousted less convenient signs d by Oughtred about the same time. A iosity is Hérigone's use of ' 2|2 ' for ' equal ', 2 ' for ' greater than ', and ' 2|3 ' for ' less than ' 34, 1644). Descartes used for ' equal ' a sign e our sign for ' varies as ', but turned the other y; the sign for ' varies as ' was introduced by Emerson (" Doctrine of Fluxions ", 3rd ed., 8). The sign × for multiplication was first d by Oughtred; the substitution for it of a ple dot is due to Leibniz (about 1698). ÷ for ision was introduced by the Swiss, Johann nrich Rahn (" Teutsche Algebra ", 1659); it l previously been used in the sense of ' minus ' lam Riese, 1525), and, very oddly, persisted in t sense in German and Scandinavian countries il the nineteenth and even the twentieth century. Oughtred first represented proportion by B :: C . D (1631); but so early as 1651 Vincent ng wrote A : B :: C : D; Leibniz substituted B = C : D in 1693. The struggle between these ations is well described (pp. 286-297), as also contest between the German + and − and the ian and French p and m for plus and minus 135-6); the latter lasted for about 130 years. competition between signs for radicals was more bewildering; " altogether there were at the close of the sixteenth century twenty-five or more varieties of symbols with which the student had to be familiar if he desired to survey the publications of his time ". The sign ∴ for ' therefore ' appears for the first time in Rahn's " Teutsche Algebra " (1659), with ∵ as a variant. This book was translated into English by Thomas Brancker and published in 1668 with additions by John Pell, the sign ∴ for ' therefore ' being thenceforth adopted, with a tendency to use both ∴ and ∵, until the latter sign came to be appropriated for ' because '. The sign ∞ for infinity was first used by Wallis (1655).

In the region of elementary geometry there have always been sharp divisions of opinion on the advisability of using symbols and the proper limits to their use. Barrow and Wallis, for example, were enthusiastic for symbols. Wallis used so many in his ' De sectionibus conicis ' that Thomas Hobbes protested: " And for your conic sections, it is so covered over with the scab of symbols that I had not the patience to examine whether it be well or ill demonstrated." . . . " Symbols are poor, unhandsome, though necessary scaffolds of demonstration . . . though they shorten the writing, yet they do not make the reader understand it sooner than if it were written in words. For the conception of lines and figures . . . must proceed from words either spoken or thought upon. So that there is a double labour of the mind, one to reduce your symbols to words, which are also symbols, another to attend to the ideas which they signify." The reaction, so far as geometry is concerned, came with Keill's and Simson's editions of Euclid (1713 and 1756). Keill, referring to Barrow's Euclid, wrote: " Barrow's demonstrations are so very short and are involved in so many notes and symbols that they are rendered obscure and difficult to one not versed in geometry. There, many propositions which appear conspicuous in reading Euclid himself, are made knotty, and scarcely intelligible to learners, by his Algebraical way of demonstration." The influence of Simson lasted until the time of Todhunter's edition.

It is a pity that, in a few cases, Prof. Cajori does not seem to have used the latest editions of the texts. Thus the form of the quotations from Diophantus and Heron on pp. 26, 27 would have been slightly different if they had been taken from Tannery's and Heiberg's editions rather than those of Bachet and Hultsch. The reference to Diophantus' " Arithmetica, vol. 4, p. 17 " should be to Prop. 16 of Book 4 of that work. T. L. H.

Plants of the Balkans.

The Plant-Life of the Balkan Peninsula: a Phytogeographical Study. By Dr. W. B. Turrill. (Oxford Memoirs on Plant Geography.) Pp. xxiii + 490 + 10 plates. (Oxford: At the Clarendon Press; London: Oxford University Press, 1929.) 30*s.* net.

THE valuable series of memoirs on plant-geography edited by Profs. Engler and Drude under the title "Die Vegetation der Erde" is familiar to every well-equipped botanist. But, as Prof. A. G. Tansley remarks in his editorial preface to the present volume, it is scarcely creditable to the Empire which possess in its dominions, colonies, and dependencies more varied vegetation than any other political entity, that Dr. Leonard Cockayne found himself obliged to publish his work on New Zealand in the German series. It is hoped that Dr. Turrill's memoir on the plant-life of the Balkan Peninsula may inaugurate a channel of publication to be known as the Oxford Memoirs on Plant Geography, and that the enterprise will be adequately supported.

Dr. Turrill's special interest in the Peninsula began with his service with the British Salonica Forces during the War, since when he has paid three visits to the area. His position as assistant in the Kew Herbarium has given ample opportunity for the detailed taxonomic work. The result is an authoritative combination of a taxonomic and ecological study of the area, embodying a vast amount of information conveyed in a more or less readable form.

The penalty of specialisation is brought home to the reader when perusing a volume such as this. The presentation of the plant-life of an area, so full of botanical interest as is the Balkan Peninsula, should appeal to every true botanist, and we would suggest to the editor that a glossary of the less common technical terms would smooth the way for the reader of those future memoirs which will, we trust, follow Dr. Turrill's.

The Balkan Peninsula is an irregularly triangular mountainous land-mass projecting from its base in Central Europe into the Mediterranean basin, and representing two main climatic areas, the Central European and the Mediterranean. Crete and the other islands to the south and east are also included in the survey. In the earlier chapters, Dr. Turrill describes in detail the physical features of the score or so of districts into which he subdivides the area, the geology and soil-characteristics, and the climate. Successive chapters are given to duration and life-forms of the species, flowering periods, habitat classification, altitudinal zonation, plant-communities, plant-succession, influence of man, cultivated crops, a summary of floristic and phytogeographical data for the families of flowering plants represented, plant-dispersal, floristic and vegetational distribution within and outside the Peninsula, and endemic and relict species and the age and area hypothesis, and finally there is a brief chapter of general conclusions.

The flora of the Peninsula is richer than that of any other area of equal size in Europe, not only in number of species but also of endemics, and amongst the latter are many relicts of the Tertiary flora. Two main types of flora and of vegetation are recognised: the Mediterranean, characterised by species adapted to surviving a summer drought, and the Central European, composed of species having a winter resting phase. The author lays great stress on the modifying influence of man, who especially by forest destruction, has induced enormous changes in the flora and vegetation. Brush-woods, heaths, stony grassland, and rock-communities occupy much ground which should, under the existing climatic conditions, be covered with high forest. Hence species suited to such habitats have been able to extend their distributional areas, and much hybridisation has resulted from their resulting contact with other species. Turrill emphasises the importance of a study of the least disturbed parts of the Peninsula, such as the Rodope massif and the Strandja Planina, before the natural vegetation is further destroyed or modified by man's exploitation.

The absence of a continuous impassable barrier separating Central Europe from the Balkan Peninsula has made the latter the most important 'area of refuge', as evidenced by the number of relict species and types, dating from Tertiary times. Owing to the comparatively small influence of the Ice Age on its flora, the botanical history of the Peninsula has been more static than that of northern Europe, and Dr. Turrill indicates its importance as a centre of species-making and dispersal, especially with regard to the ancient land-mass, the old core of the Peninsula, centred in the Rodope massif.

The illustrations include a folding map and a few photographic reproductions of the vegetation. The book is very clearly printed, but the distribution of the margins on the pages suggests that the text has slipped bodily towards the top and the effect is not pleasing.

A. B. R.

Our Bookshelf.

he Concise Oxford Dictionary of Current English. Adapted by H. W. Fowler and F. G. Fowler from *The Oxford Dictionary*. New edition, revised by H. W. Fowler. Pp. xv+1444. (Oxford: Clarendon Press; London: Oxford University Press, 1929.) 7*s.* 6*d.* net.

HIS is so far the best of the smaller and cheaper nglish dictionaries that comparison seems almost dicrous. We have a book of nearly 1500 pages, ell printed and stoutly bound, for seven and six-nce. Simply as a book, it must be the cheapest ing now on the market. But the contents de-rve a close examination, and increase at every ep our admiration.

The book is based on the great "Oxford Diction-y" which alone made it possible. The first edition, hich was published in 1911, was compiled when e great book had only reached the letter R. that time the Fowlers, who are responsible this smaller work, drew for the later letters Skeat, the "Century", and other standard books en extant. The completion of the O.E.D. has w enabled Mr. H. W. Fowler, who is alone sponsible for this new edition, to revise in e light of the latest authority. He has pro-ced a dictionary which will probably become e handy daily book of reference for everyone o writes, and is quite sufficient for ordinary ucational purposes. It contains more than ty thousand words, and abundant phrases strating their use. These are not quotations m named sources; for that one has to refer to e original work. But they are specially chosen exhibit the language as a living thing. They , in fact, rather colloquial and current than rary, and this is why the book will have its great gue and serve to build up as well as restrain the wth of English in the rising generation. It will used side by side with the same author's "Modern glish Usage".

Testing the dictionary here and there on entific words, we find that it contains more n any other of like size and scope, but that ference is given to words deriving from the er established sciences, especially mathematics, r newer words arising, say, from biology. ite a sound and useful definition is given of tegral', 'differential', 'potential', but nothing 'dominant', 'recessive', etc., in the Mendelian se. This is mentioned not so much as a fault to indicate the sort of line that has been taken. e book is a marvel of cheapness, compression, l good judgment on the lines indicated by its rce and its purpose. F. S. M.

mentary Laboratory Experiments in Organic Chemistry. By Prof. Roger Adams and Prof. John R. Johnson. Pp. xi+304. (New York: The Macmillan Co., 1928.) 8*s.*

E authors describe this book as a "laboratory nual designed for first semester students in anic chemistry". It offers a carefully planned es of practical exercises permitting of com-binations to suit various circumstances. Examples of operations illustrating the general principles of purification, etc., are followed by some forty representative preparations. Many of the latter are naturally 'hardy annuals', but we notice the introduction of *n*-butyl alcohol in an instructive sequence of operations leading up to *n*-valeric acid. Noteworthy also is the 'subjective' synthesis by the student, *in vivo*, of hippuric acid.

The experimental details and precautions are exactly stated throughout and are quite up-to-date: thus, acetaldehyde is prepared by de-polymerising paraldehyde, and valuable hints—too often omitted—are given in the accounts of acet-amide and acetanilide. The authors suggest that the inclusion of such details as the amounts of washing and drying agents to be used may arouse criticism; but probably most experienced teachers will agree that it is almost impossible to be too precise in initiating students into a correct laboratory routine in this subject. The emphasis laid in the foreword upon accuracy and neatness is also very necessary. A useful appendix contains tables of densities, etc., and also summaries of the materials and time required for each experiment. It should be mentioned that the work does not comprise the identification of organic substances.

The book is economically but adequately illus-trated, and it is well printed on a good paper which should withstand ordinary laboratory wear. The leaves are perforated and printed on one side only, so that the experimental sheets may be detached as required; incidentally, the blank pages are reckoned in the pagination. The volume can be confidently recommended as an excellent medium for effecting the introduction of students to the practice of organic chemistry. J. R.

Section de Géodésie de l'Union Géodésique et Géophysique internationale. Publication spéciale No. 2: *Tables de l'Ellipsoïde de Référence international adopté par l'Assemblée générale de Madrid le 7 octobre 1924 dans le système de la Division sexagésimale de la Circonférence.* Calculées sous la direction du Général G. Perrier par E. Hasse. Pp. 20+91. (Paris: Union Géodésique et Géophysique internationale, 1928.)

THE Section of Geodesy of the International Union of Geodesy and Geophysics decided at its 1924 meeting, in Madrid, to adopt an international ellipsoid of reference for geodetic measurements, and chose Hayford's ellipsoid, with the ellipticity 1/297·0 and major semi-axis 6378·388 km. as its primary elements. The secretariat was charged to publish tables of reference for this ellipsoid both for the sexagesimal and centesimal measures of angle: the present volume fulfils the first of these tasks. The tables, printed from typewritten sheets, are legible, well arranged, and well bound, as befits a work of reference. They give, to ten decimal places, for each minute of latitude, the logarithms of N, ρ and $\sqrt{N\rho}$, where N is the principal normal or radius of curvature of a meridian section, and ρ is the other principal radius of curvature; also, to six decimals, the logarithm of the factor of spherical

excess, the length of 1′ arcs of parallels to 0·01 mm., and, to 1 mm., the lengths of meridian arcs from the equator to each minute of latitude.

Physik: ein Lehrbuch für Studierende an den Universitäten und technischen Hochschulen. Von Prof. Wilhelm H. Westphal. Pp. xvi + 536. (Berlin: Julius Springer, 1928.) 18 gold marks.

PROF. WESTPHAL'S book is intended to be an elementary outline of physics, based upon our modern views of the structure of matter, and it is obviously based upon considerable teaching experience. It deals mainly with what we should term rather advanced intermediate physics, and the author introduces sections on entropy, the Nernst heat theorem, the electron theory of conduction, the ratio of the electrical units, thermomagnetic phenomena, the Zeeman effect and black body radiation, which are not usually found in English intermediate text-books of physics. The chapters on the quantum theory and the theory of matter and on the theory of relativity would certainly not be found in English intermediate text-books. These chapters are, of course, designed for beginners, and the former chapter even includes sections on wave mechanics and on the recent work of Sommerfeld on the electron theory of metals. The book is exceedingly well written and well illustrated. It is a book which a teacher may well recommend to an advanced intermediate student who wishes to study German.

The Science of Flight: Aeroplanes, Seaplanes and Aero Engines. By Capt. P. H. Sumner. Pp. xv + 292. (London: Crosby Lockwood and Son, 1928.) 25*s.* net.

Two years ago, Capt. Sumner published the first of his two volumes on "The Science of Flight and its Practical Application", in which he confined his attention to the development of airships and kite balloons, the scientific principles involved, and the construction and equipment of such machines. This second volume completes the review of the subject, and though his descriptions refer almost entirely to work done in Great Britain, there is a short historical chapter dealing with the early work of Lilienthal, Langley, Orville and Wilbur Wright, and other pioneers, and also with some of the memorable flights of recent years.

One chapter is devoted to the principles of aerodynamics, another to the airscrew, another to the general construction of aircraft, and a fourth to aeronautical instruments. A chapter on petrol engines in general is followed by descriptions and particulars of such famous engines as the Bristol Jupiter, the series of Armstrong Siddeley engines, the Napier Lion engine, the Rolls Royce and other engines, and the dimensions and performances of many well-known machines are included.

The People of the Twilight. By Diamond Jenness. Pp. x + 247 + 16 plates. (New York: The Macmillan Co., 1928.) 12*s.* 6*d.* net.

MR. JENNESS, as a member of the Canadian Arctic Expedition of 1913–18, spent two years with the Eskimo around Coronation Gulf. His headquarters were Bernard Harbour, and he made long visits to the little-known trade station in the south-west of Victoria Island. In these visits he cut himself off from the habits of the white man and lived the life of the Eskimo. The result is one of the most intimate studies of Eskimo habits and ways of life that has yet been published. He writes well, with sympathy for his friends and a real understanding of their problems. Although the book is meant for popular reading, it is one of the most valuable works on Eskimo life that has yet appeared. It adds much also to our knowledge of the natural history of the Canadian Arctic.

Einleitung in die Mengenlehre. Von Prof. Dr. Adolf Fraenkel. (Die Grundlehren der mathematischen Wissenschaften in Einzeldarstellungen mit besonderer Berücksichtigung der Anwendungsgebiete, herausgegeben von R. Courant, Band 9.) Dritte umgearbeitete und stark erweiterte Auflage. Pp. xiv + 424. (Berlin: Julius Springer, 1928.) 22·60 gold marks.

THE theory of aggregates is a very difficult subject on the border line between mathematics and philosophy, and many questions of the first importance are still unsettled. Indeed, it may be said that the subject is more unsettled now than when Prof. Fraenkel first published his book (1919). In this, the third edition, revised and considerably enlarged, he has endeavoured to give an impartial account of different views, including those of Russell and Whitehead, which until recently have been too little known in Germany. Finally, the author sums up and gives his own personal views but modestly mentions that these may have to be modified in the near future. Prof. Fraenkel's book appears to be one of the clearest expositions available of an extremely abstract branch of science.

Feelings and Emotions: the Wittenberg Symposium. By Alfred Adler, F. Aveling, Vladimir M. Bekhterev, Madison Bentley, G. S. Brett, Karl Bühler, Walter B. Cannon, Harvey A. Carr, Ed. Claparède, Knight Dunlap, Robert H. Gault, D. Werner Gruehn, L. B. Hoisington, D. T. Howard, Erich Jaensch, Pierre Janet, Joseph Jastrow, Carl Jörgensen, David Katz, F. Kiesow, F. Krueger, Herbert S. Langfeld, William McDougall, Henri Piéron, W. B. Pillsbury, Morton Prince, Carl E. Seashore, Charles E. Spearman, Wilhelm Stern, George M. Stratton, John S. Terry, Margaret F. Washburn, Albert P. Weiss, Robert S. Woodworth. Edited by Martin L. Reymert. (The International University Series in Psychology.) Pp. xvi + 453. (Worcester, Mass.: Clark University Press; London: Oxford University Press, 1928.) 28*s.* net.

THIS volume forms a handy means of reference to some of the more characteristic views of several distinguished psychologists. The papers, thirty-four in number, were delivered during a period of four days in the October of 1927 on the occasion of the inauguration of the new Psychological Laboratory at Wittenberg College, Springfield, Ohio.

Letters to the Editor.

e Editor does not hold himself responsible for pinions expressed by his correspondents. Neither an he undertake to return, nor to correspond with he writers of, rejected manuscripts intended for this r any other part of NATURE. *No notice is taken f anonymous communications.*]

East African Archæology.

N view of the various references to the work of East African Archæological Expedition which e appeared from time to time in the News and ws columns of NATURE during the past few nths, and with special reference to Mr. E. J. yland's letter in the issue of April 20, p. 607, we uld be grateful for the opportunity of briefly lining our results and conclusions up-to-date.

While definitely holding that there is a direct relation between the glacial phases of Europe l the Pluvials of the equatorial belt, we consider t in view of the divergencies of scientific opinion ncerning the number and sequence of European ciations, a complete correlation is at present mature.

Although preliminary work in the Nakuru-nenteita basin suggested that there had been five tinct wet periods (which we provisionally termed , 1st, 2nd, and 3rd Pluvials, with a Post-pluvial phase) more detailed investigation in this and er basins has led to the conclusion that there are y two Pluvials of the first magnitude. The first these is our original '0th Pluvial' and seems to e antedated much of the faulting in this part the Great Rift Valley. The deposits of this vial belong to the series which Prof. J. W. Gregory ludes in his Nyasan series (see "The Rift Valley l Geology of East Africa", p. 171) which he dates e think on insufficient evidence—as lower Miocene. e second major pluviation is subdivided by a dry iod of only short duration and comprises our inal 1st and 2nd Pluvials. At the close of this vial there was a period of great aridity which was owed by a renewal of pluvial conditions for a rt time. This is our original 3rd Pluvial. Another still smaller wet period is recorded by a fresh rise he lakes at a comparatively recent date.

n order to avoid the use of ordinals in referring he Pluvial periods, we have proposed the following nenclature for the Pluvial periods which we have ar recognised :

Old Name.	*New Name.*
h Pluvial.	Eburrian, 1st major Pluvial.
st Pluvial.	Enderian \ 2nd major
nd Pluvial.	Gamblian / Pluvial.
rd Pluvial.	Makalian.
ost-pluvial wet period.	Nakuran.

While avoiding for the present a more complete ial-pluvial correlation, we suggest that our second or Pluvial—the Enderio-Gamblian—can be cor-ted with the Würm (or Riss and Würm) glacia-s, or preferably with the 'Newer Drift' of northern rope. We agree with Mr. Wayland in regarding Makalian as probably the equivalent of the Bühl lium. Many implementiferous horizons have n established in the Pluvial deposits and we end a table setting out the relation of the various ures to the changes of climate. In view of the at similarity of certain of our cultures to those of Europe, we have ventured to employ the accepted European terminology while *emphasising* that by so doing we do not in any way suggest that the cultures in Kenya were necessarily contemporaneous with

Period.	Culture.
Nakuran	Contemporary: (*a*) A culture which is comparable to the Wilton of South Africa. (*b*) A culture which consists of a degenerate Aurignacian type of tool associated with pottery, agriculture, and also beads of a type which suggest a contact with one of the early civilisations. (Human type, Nakuru man.)
Makalian	A specialised form of Aurignacian culture associated with pottery. (Human type, Elmenteita man.)
Gamblian: (2) Closing stages	Contemporary: (*a*) Upper Aurignacian. (*b*) Highly specialised Mousterian, probably due to Aurignacian influence.
(1) Rise and maximum.	Contemporary: (*a*) Lower Aurignacian gradually developing into Upper Aurignacian. (Human type, Gamble's cave man.) (*b*) Upper Mousterian with a marked tendency to trimming of both flake-surfaces towards the close of the period.
Enderian	Contemporary: (*a*) Crude lower Aurignacian. (*b*) Lower Mousterian.
Eburrian-Enderian Interpluvial.	A single culture comprising large degenerate forms of ovate, very small, well-made *coups-de-poing* and flake tools with a distinct Mousterian tendency.
Eburrian: (2) Closing stages	A very fine Acheulean industry with the *S*-twist a common feature.
(1) Rise and maximum.	?

their European homologues. A large mammalian fauna has been collected from the deposits of the various Pluvials with the exception of the Eburrian, but pending investigation by a competent specialist, it is impossible to use them for correlation purposes.

The Problem of Form in Physics and Biology.

IT is not unusual to hear statements that a characteristic feature of physical phenomena, as opposed to the phenomena of life, is that the form does not play any part at all in the former, and that therefore "of all problems of physiology, that of form is the least approachable" (O. Warburg, *J. Cancer Research*, **1**, 143; 1925: quoted from V. Cofman, *Chem. Rev.*, December 1928). Without intending at all to participate in any way in the much-debated question as to the ultimate reducibility of life phenomena to those of physics and chemistry, may I point here to certain purely physical cases which, if even not yet entirely realised experimentally, are at least conceivable, and in which the form plays a very essential part.

If we consider physico-chemical systems in the state of equilibrium, the question as to the part played by the form reduces to the following: Does the free energy (or entropy, or any other thermodynamic function, the extremum of which determines the equilibrium) of the system depend on the form of the latter or not? So long as we consider systems with a small specific surface, in which the surface energy is negligible as compared with the volume energy, the answer is negative. Keeping the internal chemical constitution constant, we may alter the form of the system in any arbitrary way without changing its free energy. The form, therefore, is not a characteristic property of such a system.

If, however, we consider systems with large specific surface, in which the surface energy plays a predominant part, the situation changes. Take the trivial case of a homogeneous drop, not subject to gravity. It necessarily assumes a spherical shape, for the smaller the surface area the smaller the free energy of the system, and since the surface area depends on the shape, so does also the free energy. Of course, with the spherical form alone, there is not much done. We must therefore ask: Is the spherical form the only form of equilibrium for a free liquid system with large specific surface, and not subjected to gravity? In this connexion it may be of interest to mention (cf. my paper in *Zeitschrift für Physik*, **51**, 571; 1928) that if we consider a small droplet of any liquid, in which are dissolved several capillary active substances, we must consider such a droplet as consisting of *two* phases; one volume phase, and one 'monomolecular' two-dimensional surface phase, formed by the adsorbtion of the capillary active substances. In the general case, when the two phases may interact reversibly, it may be shown that, for a given volume V of the droplet, the total free energy of the system has a minimum for a certain definite area S_0 of the surface, which may happen to be larger than the area of surface of a sphere of the same volume ($\sqrt[3]{36\pi V^2}$). The droplet in this case assumes *any arbitary shape*, within certain limits, for then there is an infinite number of shapes, for which a body of a given volume has a prescribed surface area. The remark "within certain limits" is important. If, for example, the surface area corresponding to the equilibrium is only slightly larger than the surface area of a sphere of the same volume, then the system, though not being spherical, cannot assume, say, a form of an uniform thin long thread, for this would make S_0 too large (cf. my paper on "Systems with Large Specific Surface" in *Zeitschrift für Physik*, **53**, 107; 1929).

The most interesting cases, however, where the equilibrium of a liquid system is associated with a *definite* form, are found in investigating the possibility of interaction of such a droplet with the surrounding medium. Imagine the interior of the droplet to be the seat of chemical reactions, which result in the formation of the substances, of which the drop consists from those substances which are dissolved in the surrounding medium. These latter, assuming their solubility in the main substance of the droplet, will in these circumstances diffuse from outside into the drop, and will be 'absorbed' there, due to the chemical transformations. If the increase of the total mass of the droplet is very slow, we have the case of a quasi-stationary diffusion process, in which the amount of substances diffusing into the droplet approximately equals the amount absorbed. There is in this case a concentration gradient of these substances from the periphery to the interior of the droplet, and the distribution of the concentrations depends on the instantaneous form of the droplet. The concentration of the dissolved substances will vary along the surface of the droplet, and since the surface tension is a function of the concentrations of the dissolved substances, the surface tension will also vary along the surface. But it is possible that for a certain form of the droplet the distribution of the concentrations along the surface will be such that for all points of the surface the product of the surface tension with the mean curvature of the surface will have the same value. The corresponding form, which is itself determined by the functional relation between surface tension and concentration, and may vary widely from case to case, will be a form of equilibrium and will be automatically restored, if disturbed by a temporary external cause. The details of the mathematical treatment will appear in *Zeitschrift für Physik*.

The Mobility of Ions in Gases.

IN a recent paper (*Phil. Mag.*, **6**, 210; July 1928) I described a new method of determining the mobility of ions in gases, the principle employed being the same as that originated by Fizeau for the determination of the velocity of light. It is the purpose of the present note to describe an improvement in the previous method, giving a marked increase in both resolving power and absolute accuracy. This is obtained by the introduction of a new type of grid for producing the periodic 'shutter effect' of Fizeau.

An account of preliminary experiments with the new type of grid, which may be called a deflection grid, was given by me in a D.Phil. thesis in May 1928. In the abstract of this thesis (Abstracts of Dissertations, vol. 1, p. 126; Clarendon Press, Oxford, 1928) the work on the new type of grid was referred to. Recently the same type of grid has been described independently by Cravath (*Phys. Rev.*, **33**, 605; April 1929), who used it for a purpose other than the determination of mobilities.

The deflection grid consists of a series of closely spaced parallel bars or wires lying in the same plane. Alternate bars are connected to one outside electrode, and the remaining bars are likewise connected to a second outside electrode. Thus a slight potential difference between these two electrodes stops the passage through the grid of ions or electrons in the gas by deflecting them to the bars, whereas with no potential difference the grid is identical with one of the usual type.

A typical peak obtained by this method of mobility determination is given in Fig. 1, which shows the electrometer current as a function of the time elapsing

tween the momentary 'opening' of the first grid shutter) and the momentary 'opening' of the ond grid. As the periodic change of potential oss the deflection grids was effected by a com-ıtator of known speed and dimensions, a curve owing the theoretical resolving power may be easily nstructed. This theoretical curve is shown dotted Fig. 1. The close approximation of the experi-ental to the theoretical curve shows that the method s in practice a high resolving power, and also that,

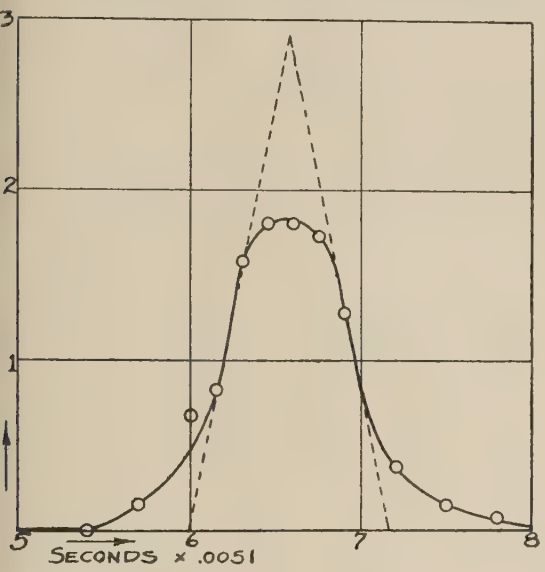

FIG. 1.

least within narrow limits, all the ions had the me mobility, which is 1·84 cm. per sec. as computed m the curve. The experiments were carried out moist air at atmospheric pressure, and the initial isation was obtained by the action of ultra-violet ht on a zinc plate.

Grids for these experiments may be conveniently nstructed by first grinding a series of parallel slots a thin glass plate, then completely silvering the face of the glass, and finally scraping off the silver ere insulation is desired.

Influence of Temperature on Raman Lines.

IN a letter to NATURE of Oct. 27, 1928, on the luence of temperature on the modified lines in ttered light, Dr. Krishnan reported that with ng temperature the intensity of the anti-Stokes es was increased relative to that of the Stokes lines, ng carbon tetrachloride as the scattering sub-nce. I have examined also the influence of tem-rature on certain organic liquids and have observed effect of another kind. When the temperature of scattering substance is increased, certain Raman es become very diffuse. Fig. 1 shows the Raman ctrum scattered by toluene at 10° C. and at 100° C., light source being a mercury lamp. Nearly all lines which appear in this figure are modified from strong Hg line, 4359, except 4617·89 and 4589·2, ich are modified from the Hg line 4047. Among m it can be seen that the doublet lines $\lambda = 4686{\cdot}82$ 4683·33 ($\Delta\nu$ from 4359 being 1607·2 cm.$^{-1}$ and 1·7 cm.$^{-1}$ respectively) become very diffuse at the high temperature. Fig. 2 shows the photomicrometric curve of that spectrum, in which noticeably affected lines are indicated by arrows. The same effect is observed in the scattering by other substances for example, benzene and carbon tetrachloride.

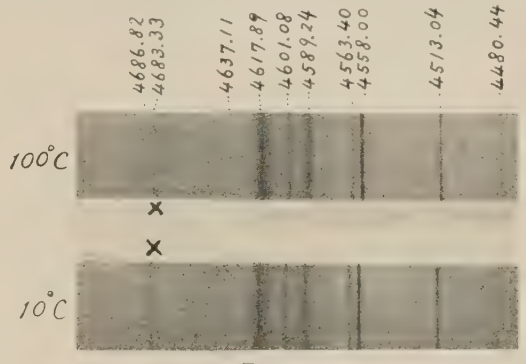

FIG. 1.

Since this broadening of the lines is not common to every line, it does not seem natural to attribute it to the Doppler effect. At all temperatures it is easily noticed with fairly large dispersion that the Raman lines caused by organic substances have several types of structure, that is, very sharp, symmetrically diffuse, asymmetrically diffuse, etc. Also, the broadening effect of temperature is, generally speaking, more noticeable on diffuse lines than on sharp lines. From these facts it does not seem unnatural to suppose that the diffuseness of Raman lines

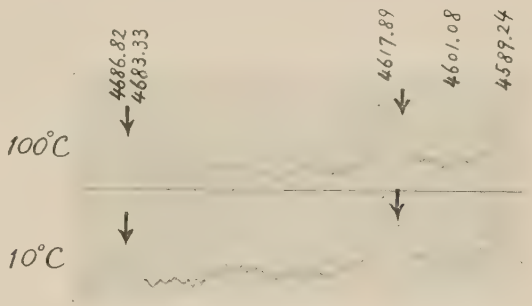

FIG. 2.

is due to molecular rotation and that the increase of temperature accelerates the rotation and causes the broadening of the lines. Further, it is interesting to notice here that in the Raman spectrum of organic substances there very often appear close doublets, and that the influence of temperature is most noticeable upon them. The above-mentioned toluene lines are one example; the doublet in benzene, 4687·10 and 4681·93 ($\Delta\nu = 1680{\cdot}9$ and 1584·4), is another example.

Sunspots and Pressure.

IN Bombay (Colaba) magnetic data, 1846–1905, Part II. (page 751), Dr. N. A. F. Moos shows that if the annual means of atmospheric pressure at Bombay are smoothed by taking overlapping means of 11 successive years, and if the smoothed 11-year means are placed at the proper epoch, the resulting variation appears to be subject to some slow period secular

change which runs fairly concurrently with that noted in the magnetic and solar curves similarly treated. I was Dr. Moos's assistant at Bombay in 1910 when the volumes were published. As time permitted I tried the 11-year smoothing process on other stations and found correlation coefficients of the smoothed means with similar smoothed means of sunspots. The stations selected, the values of the correlation coefficients, and the number of years made use of, are given in the following table :

	Tokyo.	Batavia.	Port Darwin.	Calcutta.	Madras.	Bombay.	Eniseisk.	Greenwich.	Abbassia (Cairo).	Cape Town.	Mauritius.	Charleston.	Santiago.	Cordoba.	Buenos Aires.
Correlation coefficient .	−0·65	−0·59	−0·61	−0·61	−0·27	−0·37	+0·03	−0·23	−0·61	−0·63	+0·14	+0·10	+0·32	+0·50	+0·73
No. of years . . .	47	55	43	55	55	55	50	55	52	55	50	52	55	52	55

At 6 out of the 15 stations selected the values of the correlation coefficients exceed 0·6, and the positive relationship at the South American stations is significant.

In *Indian Meteorological Memoirs*, Vol. 21, Part XII, published in 1915, on sunspots and pressure, by Sir Gilbert Walker, correlation coefficients between the annual means of sunspots and pressure are given for some 90 stations over the globe. There are only

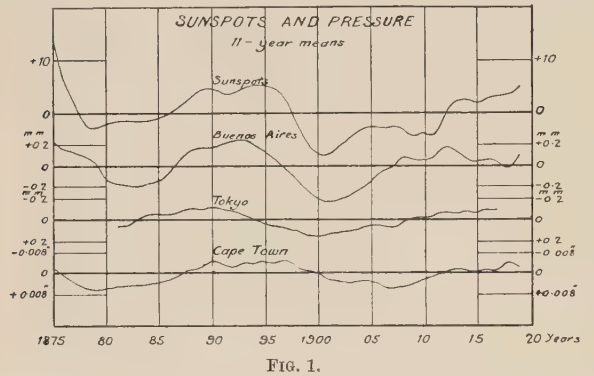

FIG. 1.

three values rising above 0·4, in two of which the number of years is only 20 or 22. The largest value, −0·47, is for Cape Town record for 55 years.

It is probable that irregularities due to various causes mask the relationship from year to year, and the 11-year smoothing process may be fruitful in leading one to the true nature of the relationship.

Curves for sunspots and for pressure at three significant stations are charted in the accompanying diagram (Fig. 1) for exhibiting the parallelism. The period embraces 5 sunspot cycles. The amplitude of the pressure range is about 0·4 mm.

Properties of the He_2 Rotation Terms.

THE analysis of the band spectrum of helium is now nearly complete. The great majority of the stronger lines have been allocated to bands, of which some sixty have now been recognised. The remaining lines may be attributed to (1) higher members of the electronic sequences already known, (2) electronic levels of a new type, and (3) vibrational levels.

In connexion with (1) a special difficulty arises, apart from the relative faintness of the lines, in that most of the bands suffer very considerable changes as the principal electronic quantum number, n, increases. Not only may the appearance of a branch entirely change (from R to Q, say), but it may fade out entirely. In some cases a band which has all three branches present for $n=3$ is reduced to a single branch (R, but of P-form) when $n=6$. The usual method of procedure, by searching for combination relationships, is then impossible, and the correctness of the interpretation proposed must remain in doubt.

The difficulty can be surmounted, in this spectrum at least, by consideration of certain regularities which are exhibited by the rotation term differences of the various electronic states. These are briefly as follows :

(1) With increasing n the differences tend to reach constant values, which in many cases may be estimated to within about 1 cm.$^{-1}$.

(2) These limiting values are identical, not only for all the terms in one system, but also for both singlet (par) and triplet (ortho) systems. They are approximately

	71	127	183	239	294	347	399	450 cm.$^{-1}$
for $(j-\rho)=$	2	4	6	8	10	12	14	16

These are evidently the rotation term differences of the He_2^+ ion, and correspond to odd values of $(j-\rho)$, the even values being missing, in agreement with theory.

(3) The ρ values associated with each electronic state follow at once from the above data, and agree throughout with those proposed by Dieke (NATURE, vol. 123, p. 716, 1929), except that for his p_b states $\rho=+1$ instead of -1 as given in his table.

It is unnecessary to give here a full description of the regularities found, but they are such that most of the rotation terms at present missing can be predicted within a few cm.$^{-1}$; conversely, the interpretation of new bands is greatly facilitated. Thus, for example, two new branches of P- and Q-form recently found by Dieke, Takamine, and Imanishi (*Zeitschr. f. Phys.*, **54**, 826 ; 1929), but not identified, are easily recognisable by this method as Q and R branches of the $6X$ level of ortho-He_2. Even single branches may now be interpreted, provided that the final electronic state is known, since it is possible to derive a set of initial term differences by combining the known final term differences with the intervals between successive lines in the branch. These differences, if genuine, will fit into the scheme and their designation will be apparent.

It is clear that this method will be of very great assistance in resolving the last complexities of the He_2 spectrum. It will be interesting to see whether it is applicable to other band spectra, and in particular to that of hydrogen.

The Heterodyne Null Method of Measuring Dielectric Constant.

It is found that different investigators using the ne heterodyne null method differ widely in their ults for the same substance. This is indicated m the results of different investigators in the cases carbon dioxide, hydrogen sulphide, and methyl oride. In a recent paper (*Phys. Rev.*, **32**; 1928) an has tried to find out the sources of this discrep-ey, and suggests that besides the calibration errors re are other possible sources of error in the method. om the data of Watson (*Proc. Roy. Soc.*, **117**; 1927), an attributes one of these to the difference in quency of the oscillating circuits which the various estigators have used. But this cannot produce a ge effect on the results. We wish to point out the ssible sources of error from our own experience for last couple of years with the apparatus we are ng for measurements of dielectric constant. They as follows :

1) The method of measuring temperature by ding the platinum wire on the glass tube con-ning the experimental condenser or on the con-ser itself (when a cylindrical condenser is used) h proper insulation, may probably produce a large or owing to the presence of this stray capacity r the experimental condenser if proper care is not en to eliminate this effect. Even if the bath which tains the experimental condenser is well earthed, l this stray capacity affects the results, and proper e should be taken to connect the experimental denser in the case of a cylindrical one. This effect been carefully studied by Sarkar (*Ind. Jour. Phys.*, 1928). He found that when the inner cylinder the experimental condenser was connected to the de of the thermionic tube it gave more concordant lts than when the outer cylinder was connected. the latter case even the movement of any other ductor or variation of current in any other circuit nected to the mains in the room would change pitch of the beat note, whereas no such difficulty observed in the former case.

Hence the method of measuring the temperature the thermo-couple is preferable. It is also found t when the thermo-couple is put into the bath frequency of the oscillating circuit changes. It herefore advisable not to put the thermo-couple the bath at the time of taking observations, and temperature should be measured just before and r the observations are taken.

2) If the bath be heated electrically from the ns, it is found that there is a difference of pitch en there is no current passing through the heating and when there is a current passing. This dently indicates a presence of stray capacity and uction effect. To avoid this, it is better to dis-nect the heating coil of the bath from the main en the measurement is to be taken.

Taking all these precautions we have found that value of the dielectric constant for dry and bon dioxide free air at N.T.P., is $1{\cdot}000579_{\pm 4}$.

The Swelling of Rubber.

SOME recent experiments on the diminution of the our pressure of solvents in rubber jellies as well measurements of swelling pressure allow us to draw e conclusions as to the nature of the swelling nomenon.

t has been found that, at the same concentration of rubber, the vapour pressure of rubber jellies from rubber of *different* origin was the same, and previous mechanical working (mastication) of rubber had also no effect on this value (P. Stamberger, *Rec. Trav. Chim. Pays-Bas.*, **47**, 316; 1928). After the mechanical working, however, the rubber swells in an unlimited manner and gives as a resulting product up to a concentration of 30 per cent a more or less viscous liquid. This behaviour shows that the solvent is not bound by surface adsorption and that there is a great resemblance to the process of molecular disperse solution. The three solvents used for these determinations were: carbon disulphide, chloroform, and benzene. The *same relative vapour pressure diminution* was found when the concentration has been calculated as grams of rubber in 1 gm. mol. solvent.

The shape of the curve in which the relative vapour pressure was plotted against the concentration differs from that expected according to Raoult's laws. The curves bend rapidly at a concentration of 20-30 per cent towards the vapour pressure axis. Although some resemblance to the ordinary process of solution was found, this behaviour suggests a process of a more complicated nature. But the affinity of the solvent for the rubber can only be due to molecular forces.

Although no difference has been found between the vapour pressure of the 'liquid' jelly of masticated rubber and the solid elastic jelly of untreated rubber, the swelling pressure of both showed *big differences*.

The liquid, masticated rubber jelly had a swelling pressure of 35 cm. of mercury at a concentration of 0·4 gm. rubber in 1 c.c. of solvent (toluene), the unmasticated had the same swelling pressure at a much lower concentration, 0·11 gm./c.c.

This value shows that the swelling of a structureless (masticated) rubber differs greatly from the swelling of a rubber having a definite structure, although both show the same vapour pressure diminution. For this reason it is not possible to calculate the swelling pressure from the vapour pressure diminution on a simple thermodynamic basis.

This behaviour shows that the forces which cause the imbibition of solvent by the jelly are not of a uniform nature and the 'structure factor' has an influence when the solvent is present in a liquid form (P. Stamberger, loc. cit.).

Particulars of this investigation will be published shortly.

The Isotopes of Oxygen.

I HAVE recently been studying the vibrational energy functions of molecules, in connexion with a recalculation of heats of dissociation, and have noticed that the equation given by Dieke and Babcock (*Proc. Nat. Acad. Sci.*, **13**, 670; 1927) for the upper level of the atmospheric bands of oxygen has an unusually large coefficient for the n^3 term. This, I now find, is due to an arithmetical error of 2 cm.$^{-1}$ in their location of the origin of the $O - O$ band. The correct figure should be 13,120·97 cm.$^{-1}$, instead of their 13,122·97. The correction not only leads to the expected small coefficient for n^3, but also brings their data into good agreement with the older constants, as given on p. 232 of the "Report on Molecular Spectra in Gases". The resulting corrected equation is

$$E_n = 13{,}120{\cdot}97 + 1418{\cdot}69n - 13{\cdot}925n^2 - 0{\cdot}02n^3 \quad (n = 0,\ 1,\ 2,\ 3),$$

as contrasted with their

$$E_n = 13{,}122{\cdot}965 + 1415{\cdot}017n - 11{\cdot}911n^2 - 0{\cdot}3525n^3$$

The new constants are of importance in connexion with the isotopes of oxygen. Giauque and Johnston

(NATURE, Mar. 2, 1929) found that the assumption of $O^{16} - O^{18}$ and $O^{16} - O^{16}$ as the two molecules concerned, led to a calculated isotope splitting, in the $O - O$ band, which averaged 0·05 cm.$^{-1}$ greater than the observed splitting. (From their original data I find that the average is 0·053 cm.$^{-1}$, for the 25 lines used.) The change in the vibrational constants just given lowers the calculated splitting by just 0·067 cm.$^{-1}$, making the discrepancy now only 0·014 cm.$^{-1}$ in the opposite direction.

More recently, Giauque and Johnston (NATURE, June 1, 1929) have interpreted faint lines in the $O - O$ band, newly found by H. D. Babcock (*Proc. Nat. Acad. Sci.*, in press), as due to an $O^{16} - O^{17}$ molecule. The calculated isotope splitting is again too large, in this case by an average of 0·03 cm.$^{-1}$, although the faintness of the new lines makes the probable error much larger than in the previous case. The change in vibrational constants lowers the calculated splitting 0·036 cm.$^{-1}$, and so practically cancels the discrepancy. One can accordingly conclude that there is now perfect agreement with the theory, on the basis of 16, 17, and 18 for the atomic weights, and half-integers (on the *old* quantum theory) for the vibrational quantum numbers.

Babcock's measurements of relative intensity (NATURE, May 18, 1929) indicate that O^{16} has an abundance at least 1250 times that of O^{18} (see Giauque and Johnston, NATURE, June 1, 1929). The O^{17} atom, according to Babcock's work, is much less abundant than O^{18}. On the basis of these figures, Aston's determinations of atomic weights, made with his mass spectrograph, should be not more than one part in 10,000 greater than the chemical values.

	Mean . 3·052 A.		Mean . 3·054 A.		Mean . 3·061 A.	

[1] The equilibrium diagram of this system studied by Prof. K. Iwasé and N. Aoki will appear in *Science Reports* of Tôhoku Imperial University, Sendai.

The densities observed for 43, 50, and 55 per cent antimony are respectively 6·9084, 6·9100, 6·9109. The number of atoms contained in a unit cell is calculated to be 0·9918, 0·9993, and 0·9908, being very nearly equal to 1. This fact and the spectral indices confirm that the crystal structure of these alloys is a simple cubic lattice. From the result of the X-ray analysis it is concluded that the range lying between 43 and 55 per cent of antimony is a solid solution of this compound and one of the components. It is only very rarely that a metallic compound has a simple cubic lattice. ATOMI ÔSAWA.

Imperial University, Sendai.

Heterogonic Growth in the Appendages of Crustacea.

PROF. J. S. HUXLEY and Miss Tazelaar find (NATURE June 15, p. 910) that the appendages behind the enlarged male chela in *Inachus* and *Palæmon carcinus* show a slight acceleration of growth, while those anterior to it show a slight retardation. They express this as "an influence on the growth gradient by the axial relations of the whole animal". I presume that this is merely a way of expressing a purely empirical correlation, and therefore I do not understand what is meant by suggestions bearing on the mechanism of this influence. What is the mechanism of the influence which produces the original heterogonic growth centre near the tip of the large chela ?

Empirically the heterogonic growth of the large chela is correlated with greater muscular activity on the part of this chela in the male as compared with the female. It seems to me the important question is whether the acceleration of growth in appendages posterior to the chela is correlated with greater activity of those appendages as compared with those anterior to the chela. As for 'mechanism', it is generally agreed that the heterogonic growth in the individual crustacean is due to some endocrine effect associated with the male gonad or with the sex-chromosomes. Surely whatever the mechanism may be which causes the heterogonic growth of the large chela, that of the appendages posterior to it is due to the same mechanism. I see no reason for assuming that the accelerated growth of the latter is a secondary effect of that of the large chela.

Hermaphrodite Oysters.

THE interesting question of hermaphrodite oysters was raised in NATURE of June 8 by Mr. I. Amemiya.

On this subject it is appropriate to make the following remarks :

1. In 1854, Lacaze-Duthiers (*Ann. Sci. nat. Zool.* ser. 4, ii., p. 217) pointed out the hermaphroditism of the small *Ostrea stentina* Payr., synonymous with *O. plicatula* Gmel. and *O. plicata* Chemn., for malacologists generally.

2. In 1911 an undeterminable *Ostrea* (*O. sp.*) from Saleh Bay (Sumbawa) was quoted as hermaphroditic ("Siboga Expedit.", Part 53 *a*, pp. 27 and 102).

3. In 1926, Gutsel (*Science*, **44**, p. 450) described the hermaphroditism of *Ostrea equestris*.

4. With *O. edulis*, *O. angasi*, *O. lurida* and *O. densela mellosa*, there are, so far, only seven hermaphroditic species in the great genus *Ostrea*, or a very small number in comparison with the dioïc forms in the same genus. The latter are very numerous indeed, namely, all the species of the 'subgenera' *Alectryonia* and *Gryphæa*, and also some others which are not related to these two groups. PAUL PELSENEER.

The Distribution of the Chemical Elements.[1]

By Dr. V. M. Goldschmidt, Professor of Mineralogy, Oslo.

)ETROLOGISTS generally agree that the earth contains a core of an iron alloy, most probably ckel iron with about 8 per cent of nickel, in analogy the most common types of iron meteorites. Below e common silicate rocks of the crust there is obably a region of enrichment of heavier sili-tes, which have separated by crystallisation from olten silicate magma, and have settled downward ving to their high specific gravity. Probably the ineral olivine is present here in substantially rger amounts than in the average surface rocks. does not explain the fact that there seems to be a very distinct boundary to the iron core, and also a marked discontinuity against the silicate mantle. It seems also improbable that two substances of so different density as iron and silicate, originally present in a molten state, would not have separated in the earth's field of gravity. The possibility must be considered that this intermediate shell largely, or at least to a considerable part, contains sulphides and oxides of heavy metals, especially the mono-sulphide of iron, a substance we even observe as a

Radial Thickness.	Density.	Name.	Main Chemical Features.	Main Physical Features.	Which Group of Elements is Concentrated.
Several 100 km.	0-0·0015	Atmosphere	Nitrogen, oxygen, water vapour, carbon dioxide, rare gases	Gas	Atmophile
0-11 km.	about 1	Biosphere	Organic substances and skeleton minerals	Solid and liquid, often in colloidal division	Biophile
0-11 km.	1	Hydrosphere	Oceanic and fresh water with dissolved salts and gases, snow and ice	Liquid (in part solid)	Atmophile (and some lithophile)
30-120 km.	2·8	Earth's crust of silicates	Ordinary silicate rocks	Solid	Lithophile (of late crystallisations and mother liquors)
1100 km.	3·6-4	Eclogite shell	Silicate rocks, probably rich in Mg_2SiO_4	Solid, very dense crystalline arrangements of atoms (eclogite facies)	Lithophile (of early crystallisations)
1700 km.	5-6	Sulphide - oxide shell	Characterised by large amounts of sulphides and oxides of heavy metals, especially iron	Solid	Chalkophile
3500 km.	8-10	Nickel iron core	Alloy of iron and nickel	Solid (in part liquid ?)	Siderophile

ncerning the physical state of matter in this avier silicate shell underlying the earth's crust, know with certainty that it is in the solid state, d that certain crystallised silicates and other nerals must be present in a peculiar state of high nsity owing to pressure, which is characteristic the eclogite facies, as deduced by Fermor and kola, and recently most convincingly demon-ated by P. Wagner.

Between the eclogite shell and the iron core there still another mighty shell, separated from the ogite shell and from the iron core by surfaces discontinuity detected by measurements of the pagation of seismic waves. By many petro-ists this shell is considered to be a mixture of cate and nickel iron. This opinion, however, distinct separate phase in a very large number of meteorites.

From many basic igneous rocks in the earth's crust molten sulphides segregate as separate sul-phide magmas. Any such sulphide magma will tend to migrate towards the zone between the iron core and the silicate mantle, so that in this region of the interior of the earth there would accumulate the major part of sulphidic compounds, mainly iron monosulphide, together with heavy oxidic minerals, especially oxides of iron and chromium, which separate from silicate magmas at early stages of crystallisation.

Outside the silicate shell or lithosphere, there are further envelopes of our earth, the hydro-sphere and the atmosphere, and on the boundary between the lithosphere and atmosphere, as well as intergrown through the hydrosphere, there is a

[1] From a discourse delivered at the Royal Institution on Friday, 15.

last, and from the human point of view a most important sphere, the biosphere, the zone of organised organic substance, the zone of life.

Our earth thus is separated into a number of shells, arranged in the order of density, as shown by the table on p. 15.

Men of science agree that our solid earth must once have been in a molten condition to enable the density distribution which prevails to-day to be formed. Already in times older than geological record, in the early 'astronomical' age of the earth, the subdivision of the molten planet, surrounded by a gaseous envelope, into several liquids, must have begun, followed by separation of the different liquid phases according to gravity. The distribution of chemical elements between the three liquids and one gaseous phase may now be considered from the viewpoint of physical chemistry; we may try to find the quotients of partition in the four-phase equilibrium. Such volatile elements, which have no very great affinity to the substances of the three liquid phases, will accumulate in the gaseous envelope, such as, for example, argon and nitrogen; also compounds with similar properties, as water and carbonic acid, will enter the primordial atmosphere. All these substances may be called *atmophile*. Many chemical elements gather in the silicate magma; they are *lithophile* elements. The most prominent element is oxygen, constituting 62 per cent of the numbers of atoms present, or even 92 per cent of the volume of the earth's crust. The only heavy metal entering in appreciable amounts into the silicate shell is iron, about 2 atomic per cent of iron being present.

Next we shall consider the elements which are concentrated in the molten iron; we may call them *siderophile* elements. These are elements having a great solubility in molten iron, either as uncombined elements or as chemical compounds, such as nickel, platinum, carbon, phosphorus. Lastly, we may consider the elements which enter into molten iron sulphide; we may give them the name *chalcophile* elements. Such elements are, for example, copper, silver, lead, bismuth, selenium.

The actual amount of metals and of non-metallic elements in the earth as a whole has resulted in sulphuration and oxidation of part of the iron. We find iron in large amounts in the sulphide phase, and even to some extent in the silicate phase. Therefore, the partition of all other metals will be dependent on their affinities to oxygen and to sulphur, compared with those of iron. If an element is more siderophile than iron it will enter into the nickel-iron core; if it is more chalcophile than iron it will concentrate in the sulphide phase; if its inclination to enter into oxygen compounds is greater than that of iron it will accumulate in the silicate slag. Iron, therefore, is a kind of measure of geochemical affinity.

It would be interesting to know whether the rarity of precious metals is real, or if it is due to special quotients of partition which might have concentrated such metals as gold and the platinum metals, in the interior of our planet. Especially it would be a matter of importance to ascertain if the elements of the platinum group really are so very rare as they appear to be from most analysis of terrestrial matter. The average amount of platinum in the average silicate rocks may be considered to be of the order of 1 to 1000 millions, that is, about 1 gram in 1000 tons of rock. We may, without any doubt, predict that platinum and the other siderophile metals of the platinum group must be found in very much larger concentrations in iron meteorites, if the present distribution of elements is due to an equilibrium of partition. By the microdocimastic methods of analysis, worked out for our geochemical work by Dr. Lunde and Mrs. Johnson Høst, a large number of terrestrial rocks and of meteorites were analysed for precious metals by Mrs. Høst in my laboratory. Some data from her determinations illustrate the amount of platinum metals in meteorites:

Iron Meteorites.	Total Platinum Metals.
Arispe	117 grams per ton.
Savik, Cape York	75
Mount Joy	68
	54
Mukerop	38
Toluca	25
N'Goureyma	2
	2

Silicate Meteorites.

Juvinas	No platinum metals, no silver, no gold. Total precious metals less than 0·05 gm. per ton.
Stannern	No platinum metals, no silver, no gold. Total precious metals less than 0·05 gm. per ton.

These data, and many others, demonstrate that the platinum metals are not to be considered as very rare elements, but that their relative rarity in terrestrial surface rocks is only a consequence of their partition between nickel iron and silicates.

The quotients of partition between the different phases for any given element must be dependent on the properties of this element, and we may expect to find general relations between geochemical distribution and the properties of atoms and ions. If we plot a diagram showing the atomic volume of the chemical elements as a function of atomic number (nuclear charge), we find the following correlation between geochemical character and atomic volume. The typical siderophile elements are found at the minima of atomic volume, as, for example, carbon, phosphorus, iron, ruthenium, platinum. The typical atmophile elements tend towards the maxima of atomic volume, such as hydrogen and the rare gases. Lithophile elements occupy the descending branches, where we find the typical ion-forming elements such as magnesium and calcium. In the ascending branches of the curve we find the typical chalcophile elements, for example, copper and selenium. These regularities seem to be connected with different types of electronic arrangement in the several types of atoms and ions. If there exist elements following after uranium in atomic number, they are probably siderophile, and for this reason they may be absent or nearly absent from the rocks of the earth's crust.

We have seen how the present distribution and

pparent frequency of chemical elements may be rgely due to the laws of partition between the ur phases, a separation which has taken place the very early history of our earth. As cooling roceeds there comes into action a new kind of paration, which has no precedents in the earlier istory of our earth, namely, *fractional crystallisation*. Among the first products of separation are inerals with low solubility in the silicate magma nd high melting points, such as chromite and livine; then follow other iron ores, together with he bulk of pyroxenes and plagioclase felspars; ter on the pyroxenes are succeeded by amphiboles nd biotite; and the basic plagioclases are followed by acid ones and by potash felspar, with uartz and muscovite. At last only pegmatitic agmas and aqueous solutions remain as a kind f mother liquor of the magma, from which rystallise coarse pegmatitic dikes and hydrothermal mineral veins, and from which also gaseous onstituents may escape, giving rise to pneumatoytical minerals.

Whilst the partition into atmophile, lithophile, tc., groups had taken place between amorphous hases, as gases and liquids, the process of fractional rystallisation involves the presence of crystalline hases, and the properties of atoms and ions in rystalline arrangements must be of deciding imortance for the fate of the different elements. he distribution of any given element between a quid phase and a coexisting crystalline phase ill depend on isomorphism between the element or its ions) with the components of the crystalline hase. Now isomorphism, as crystallographers have nown for a very long time, is mainly dependent on he volume of the different kinds of atoms or ions, nd the question of partition therefore leads to a elation between atomic and ionic sizes and geohemical distribution. Therefore, from the geohemical point of view, it is most important to get xact determinations of the radii of atoms and ions n crystals. The formation of crystals will effect sieving or sorting of elements, and this process f sieving may determine the fate of any rarer lement present, including both lithophile elements nd the small amounts of siderophile and chalcohile elements which have entered the molten ilicate.

We must also consider the very important case hat the rare element does not enter the crystal, ut is forced to remain in the liquid. In this anner a number of rare elements are concentrated n the mother liquors of magmas. There they remain ntil their concentration reaches the saturation limit f their own crystalline phases; then they are recipitated as minerals of rare elements. This xplains why, in the mother liquors of silicate agmas, the pegmatite magmas, we encounter such wealth of rare elements. If our principle conerning the relation between fractional crystallisaion and the sizes of atoms and ions is sound, we hall expect to find *two very different types* of rare lements in the mother liquors: those which are of *ery small* size compared with current atomic and onic sizes, and those which have *very large* sizes. This is in the very best accordance with mineralogical experience.

The specific gravity of the liquid part of an ordinary silicate magma, which undergoes processes of fractional crystallisation, decreases substantially as crystallisation proceeds, owing to the high density of the earlier minerals and to the increase in volatile components (as water and carbonic acid) in the mother liquor. Residual magmas and associated aqueous solution will thus have a strong tendency to migrate upwards to the uppermost levels of the earth's crust, and heavy minerals of early crystallisation will tend to sink down towards deep levels. Therefore, in the highest levels of the silicate shell we encounter a relative enrichment of those elements that are concentrated in the light granitic rocks and residual solutions of the magmatic sequence. For this reason many of the rare elements, which are typical for pegmatitic associations, are found in comparatively high concentrations in the uppermost levels of the atmosphere.

The fact that chemists have been able to detect not less than 89 out of 92 possible elements is surely due to the circumstance that the processes of distribution, acting in a strong field of gravitation, have been very favourable for accumulating even very rare lithophile elements in considerable amounts near the surface of our earth. Also, the distribution of the radioactive elements, with a marked enrichment of uranium and thorium in the light rocks of very high levels, is in complete accordance with the principles of geochemical distribution.

An investigation of the present distribution of chemical elements, however, cannot be limited to the study of inorganic nature; there is at work one more factor—the youngest in the story of geochemical evolution—that is, the organic world, the *biosphere* of the earth. Living organisms need a number of elements for the construction of protoplasm and auxiliary substances; we may mention carbon, hydrogen, oxygen, phosphorus, sulphur, chlorine, together with small but indispensable amounts of rarer elements such as iodine. Under most varying conditions of life, organisms have shown their ability to concentrate and utilise the different types of necessary substances; they have become one of the important factors regulating the distribution of chemical elements. Especially for such elements which in the original inorganic matter are present only in more modest concentrations, such as phosphorus or iodine, or fixed nitrogen, organic Nature has become a dominating factor of distribution.

We may become conscious of the importance of organic life in geochemistry if we consider that our present atmosphere, containing a large amount of oxygen and only traces of carbon dioxide, may have got these features largely through the action of plant life on the primary atmosphere of our planet. We may particularly refer, in this connexion, to the ever-increasing activity of man in utilising the resources of our earth, thereby greatly altering the distribution of elements within the reach of his power.

The North-East Coast Exhibition at Newcastle-upon-Tyne.

THIS is an exhibition with a purpose ; it is the gallant attempt of a depressed area to help itself. The genesis of the idea was inside the Chamber of Commerce on Newcastle Quayside ; afterwards it was taken up by the Lord Mayor and Corporation ; it has been carried through by the leaders of industry working as citizens in committees under a general council representative of the associated cities. The idea is the quest for business through associated advertisement and salesmanship.

The Exhibition is in a corner of the Town Moor behind the Hancock Natural History Museum and about a mile from the Central Station. It is easily accessible by tram. Turning round for a moment before entering the gates, Armstrong College and its new Mining Department are seen 300 yards away. Just inside the Exhibition turnstiles a kiosk supplies an "Official Guide" (price 3*d*.) with a plan of the main buildings. These include Palaces of Engineering, Industries, and Arts, a Festival Hall for conferences, a Stadium for boy scouts, an Amusements Park, and the sideshows of the evening newspapers. An "Official Catalogue" (price 1*s*.), bought before leaving and studied at home, will save time on a second visit. This contains the names and portraits of the organisers, a list of exhibits, plans, and full indices. It is a very handy volume, indicative of excellent general organisation. A more bulky "Exhibition Year Supplement" of the *Newcastle and Gateshead Chamber of Commerce Journal* (price 2*s*. 6*d*.), is obtainable in the Guildhall on the Quayside. It contains a trade index of industries with illustrated advertisements. It seems valuable for strangers intending to place large orders or inquiring into the industrial environment before choosing sites for new works.

The natural products of the area include not only coal but also whinstone and limestone for roadmaking, freestone for building, grindstones from the millstone grit, lime from both carboniferous and magnesian limestones, magnesia from the latter, fireclay from beneath the coal, brick-clay from nearer the surface, brine from the trias, and ironstone from the oolite. Navigable estuaries admit shipping and encourage shipbuilding, deep river gorges have stimulated the bridge builders, Cleveland iron-stone and Durham coal have made the Middlesboro' iron and steel industry which supplies material for all the engineering works. Tyneside was the birthplace of Stephenson and of the locomotive. More lately the district has been to the front in the production of high tension electric supply in alternators driven by Parsons turbine machinery, and this electric current has been applied to railway traction and through a grid for other industrial purposes.

The greatest engineering triumphs will not fit into exhibitions. The new Tyne Bridge with roadway slung from an arch apparently parabolic is seen when entering Newcastle from the south. The *Mauretania* and its floating dock may be seen at Southampton. The latest colliery improvements are in the collieries and at work. Locomotives and rolling stock are on the railways. Within the Palace of Engineering these greater objects can only be represented by pictures and models ; 30 tons has been the limit, a steam rail coach brought in by the London and North-Eastern Railway Company. A few other exhibits are here named as samples, not as a catalogue.

Sir Howard Grubb, Parsons and Co., show a reflecting telescope of 3-feet aperture intended for the Royal Observatory, Edinburgh. It is designed in accordance with specifications by Prof. R. A. Sampson, and is to be used chiefly for spectroscopic work. The parabolic mirror and auxiliary hyperbolic mirror combine to make an equivalent focal length of 54 feet. The driving circle is clamped to the polar axis by hydraulic pressure. The driving clock has both its own frictional governor and also a control by impulses received every second from an observatory timekeeper.

Messrs. Reyrolle and Co. have specialised on switch-gear for large electric power stations. With voltages of 33,000 the contacts are made and broken under oil and inside earthed metal-clad cases.

Imperial Chemical Industries explain, by means of a cinema hall, what their associated companies are doing at Billingham. Pictures show how the fertilisers make the grass grow in intensive culture paddocks. Specimens of various products are shown, Billingham carbonate of lime, nitro-chalk and imported nitro-phoska, chlorine for water purification, Portland cement, etc.

The Thermal Syndicate is an example of a new industry made possible by electric supply. Its 'vitreosil' or fused silica finds increasing applications due to its high melting point, low coefficient of expansion, transparency to ultra-violet light, non-conduction of electricity and resistance to acid. The size of worm-tubes for condensation has greatly increased. Also for laboratory use is the Pyrex glass made in Sunderland. There are numerous domestic electrical appliances for heating and cooking. The Electric Lamp Manufacturers' Association is advising on the best methods of industrial lighting.

Among recent developments of driving machinery are the Diesel and half-Diesel engines. A new Doxford engine has no closed ends to its cylinders but two pistons both moving outwards. The great production of metal work has been a stimulus to paint, enamel, and anti-fouling compositions. A coke maker is using X-rays to detect unseen impurities. A toffee-making machine, automatic with endless band, attracts attention. But it is not only the toffee and the toffee-making machine that matter. Behind it stands the maker of the toffee-making machine, and the possibility of inventing other machines with continuous output at increasing profits for other industries. Unfortunately, unlike a toffee works, a coal-mine exhausts its product ; it cannot expand indefinitely, it must finance its sinking funds on other principles. This and other

Cosmical Magnetic Phenomena.[1]

By Prof. S. CHAPMAN, F.R.S.

MAGNETISM on a grand scale in the cosmos has been observed only on the sun and earth. The earth's magnetism has been studied more than three centuries; Gilbert's treatise it, published in 1600, was the first book on dern experimental science, and his recognition t the earth is a great magnet preceded Newton's covery of universal gravitation. Solar mag-ism was first detected twenty-one years ago,[2] l all our knowledge of it comes from a single ervatory.

The measurement of the sun's magnetic field is irect. It depends on the influence, called the man effect, which the field exerts on atoms tting or absorbing light. Certain lines in the ar spectrum are split up, or broadened, by an ount which indicates the magnetic intensity at sun's surface. From this it is easy to calculate maximum possible intensity of the sun's mag-ic field near the earth, and to show that it is small to be measured directly.

The sun is intrinsically a typical star, though its netary system is exceptional. It is therefore bably not the only star possessing a magnetic d. The marvellous advances already made in conomical technique give hope that, in time, lar magnetic fields may be detected, but at sent the measurement of even the sun's field is y difficult.

Lunar and Planetary Magnetism.

t is natural to inquire whether the moon and nets have magnetic fields. The moon is not -luminous, and has no absorbing atmosphere, so t indirect detection of its field by means of the man effect is not possible. It is doubtful also ether the Zeeman effect will be measurable on of the planets. Hence, unless we can measure *ctly* the lunar and planetary fields in the earth's ghbourhood, they are likely to remain unknown.[3] v the field-intensity near the earth, due to a ere of radius a at distance d, with average nsity of magnetisation I, is $\frac{4}{3}\pi I(a/d^3)$. This ies as the cube of the angular radius of the ere (a/d), as viewed from the earth. The moon, ch has a much larger angular radius than any net, is therefore the body most likely to exert a surable magnetic force near the earth. A weak ernal field would be difficult to disentangle from the earth's field, if it were uniform and constant, but the moon's field would be neither of these. It would reveal itself in two ways: owing to the varying distance of the moon as it moves in its rather eccentric orbit, there would be a *monthly* magnetic variation, while the earth's rotation in the slightly non-uniform lunar field would produce a lunar *daily* magnetic variation.

Lunar periodicities in the earth's magnetism have been minutely studied; a lunar *daily* magnetic variation does occur, but it is an indirect effect of the tidal action of the moon on the earth's atmosphere. No variation of the type which a lunar magnetic field would produce directly has been found; if the intensity of the field near the earth were so great as 10^{-4} gauss (or 10γ) it would scarcely have escaped notice. This indicates that for the moon the value of I cannot exceed 100; for the earth I is 0·1, and a value for the moon 1000 times as large as this was in any case scarcely to be expected;[4] in other words, the failure to detect the moon's field near the earth was *a priori* likely. The same applies still more strongly to the planets, and though planetary periodicities in the earth's magnetism have been sought for, none has ever been found.

Cosmical magnetic phenomena, as actually observed, are therefore either terrestrial or solar. Their study demands, first of all, accurate, detailed and long-continued measurements. Then the observations must be reduced by systematic analysis to a much smaller ordered body of facts. This process involves great labour, and is still incomplete, even in the case of the earth. Some important features of the phenomena can be readily perceived, but others have been found only by long computations and minute comparisons with related phenomena. The final task is to explain the facts in terms of general physical laws; this has proved very difficult, and most of the problems of cosmical magnetism remain unsolved. Mathematics is essential in the theoretical discussion; the large scale of the phenomena almost always precludes an experimental test of proposed hypotheses; their consequences, which must be compared with observation, can only be calculated.

Terrestrial Magnetism.

While the study of the sun's magnetism is still in its infancy, terrestrial magnetic science has a

[2] By Hale at Mount Wilson, California.
[3] There is a faint possibility that they may be detected by their eting influence on streams of charged particles which issue from un and afterwards fall on the earth.

[4] The magnetic intensity at the surface of a sphere is proportional to I, and if I for the moon were 100, the intensity of its field at its poles would be about 800 gauss, or more than ten times the intensity of the sun's magnetic field.

long history. Seamen, clockmakers, explorers and others have gradually accumulated the great store of data that we now possess; these have been charted and analysed by numerous workers, and have provoked a long series of theoretical speculations. During the Middle Ages the directive property of the compass was generally ascribed to an influence proceeding from the heavens, sometimes even from a particular star; but in the year 1600 William Gilbert, of Colchester and St. John's College, Cambridge, showed that the cause is terrestrial. His proof was simple and convincing; he took a spherical piece of loadstone and explored its field by means of small pivoted magnets; they set themselves in relation to the sphere just as compass needles do in relation to the earth, showing the observed distribution of magnetic dip (Fig. 1); hence he inferred that the earth itself is a great magnet. He had the good fortune to be dealing with one of the few physical properties of a large globe like the earth that can be easily illustrated by a small model.

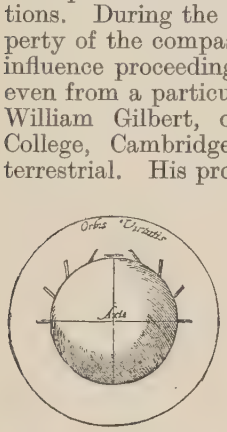

FIG. 1.—Reproduction of a woodcut from Gilbert's "De Magnete" (English translation, 1900).

Subsequent observations have shown that the compass direction can depart more widely from the true north than Gilbert supposed. The earth's field does nearly resemble that of a spherical magnet, but the magnetic axis is inclined at about 12° to the axis of rotation. In addition, the field is

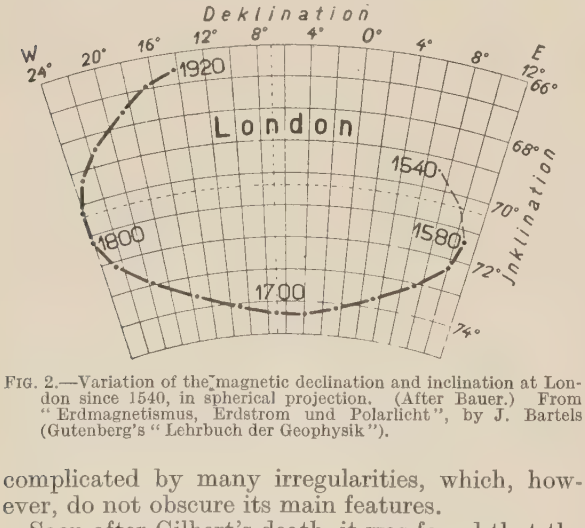

FIG. 2.—Variation of the magnetic declination and inclination at London since 1540, in spherical projection. (After Bauer.) From "Erdmagnetismus, Erdstrom und Polarlicht", by J. Bartels (Gutenberg's "Lehrbuch der Geophysik").

complicated by many irregularities, which, however, do not obscure its main features.

Soon after Gilbert's death, it was found that the earth's field is not constant. The secular change in the *direction* of the magnetic force has been measured at a few places for more than three centuries, but the data for the first two of these are scanty. Measurements of the *intensity* of the field extend over little more than a century. The change in the direction of the force at London since 1540 is shown in Fig. 2; the variation appears to be fairly regular, and possibly periodic; if so, the period is not less than five centuries. It has been supposed that th secular variation largely consists of a rotation of th earth's magnetic axis round its axis of rotation, bu the observations do not warrant this inference (cf Fig. 3). They suggest rather that the secular varia tion, though a large-scale phenomenon, is regiona and not world-wide in character. Its most notabl property is its rapidity: large-scale changes in th state of the earth are in general much slower tha the magnetic variation. The earth's magnetisatio seems to have decreased by about 5 per cent durin the century for which observations of the intensit are available; at present the decrease is proceed

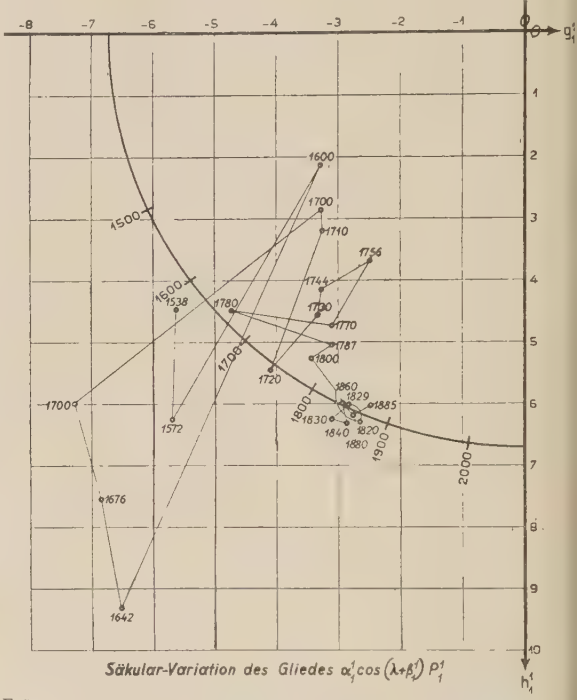

FIG. 3.—Variation, in magnitude and direction, of the transverse com ponent of the earth's magnetism, which mainly determines th obliquity of the magnetic axis. The determinations before 182 are very uncertain, and the subsequent change in direction of th axis is small.

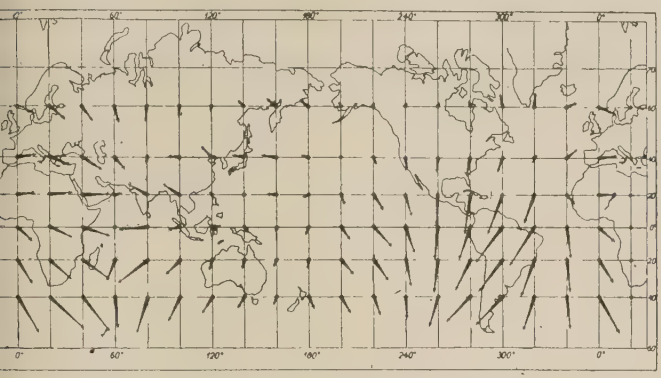
ing most rapidly in the southern hemisphere (cf Fig. 4).

On the basis of our present knowledge, it is im possible to guess the past or predict the futur course of the earth's magnetism. Three centuries i a trivial fraction of the life of the earth, and worker on terrestrial magnetism may envy astronomers whose observations extend over thousands of years Geologists, who have the age-long record of th rocks at their disposal, are still more fortunate There is hope, however, that the rocks may revea also something of the *magnetic* history of the earth

Just before volcanic lava solidifies, it acquire induced magnetism along the direction of the earth' field; afterwards its magnetism is believed to re main constant. Mercanton, of Switzerland, ha determined the direction of magnetisation of lav specimens carefully cut out from deposits, in man parts of the earth, which appear not to have bee tilted or distorted since they were first formed. H

erefore infers the direction of the earth's field, ative to the lava deposits, at remote geological ochs. Large deviations from the existing relative ection of the field are found, the difference some- nes almost amounting to a reversal. Can the rth's magnetism really have changed its sign ring geological time? One is tempted to say



g. 4.—Annual secular variation of horizontal magnetic force at epoch 1922 (after Bartels): scale 200γ per cm. (approximately).

, but the denial is unjustified while we know so le about the cause of the magnetic field. Other erpretations of the evidence may, however, be ssible; though the lava may not have been tilted distorted, it may have moved or turned bodily, a horizontal plane, relative to the field. If the ssibility of such motion can be excluded, or if e motion can be estimated, our knowledge of e earth's magnetic history may be greatly ex- nded.

Gilbert's comparison of the earth with a spherical dstone gave a concise representation of a multi- de of isolated magnetic measurements. It could t establish a physical theory of the earth's gnetism, but it was the first contribution to the ddle, systematic, stage in the development of restrial magnetic science. His demonstration of e internal origin of the field was confirmed and ndered more precise, 240 years later, by Gauss. a memoir which, like Gilbert's treatise, marked epoch in physical science, Gauss applied the eory of the potential, and the method of spherical rmonic analysis, to the earth's magnetism. He owed how from a knowledge of the distribution magnetic force over the earth's surface it is pos- le to determine whether the origin of the field internal or external, or both, and, in the latter se, how to evaluate the two separate parts. th the limited data at his disposal, he was ntent to show that the observations, including ir departures from the field of a spherical mag- , were consistent with an internal origin. Later alyses, with better data, restrict any possible ernal part of the surface field to about 3 per nt of the whole; there may also be a similar all fraction which does not possess a potential, d is therefore due to electric currents *crossing* the face, from earth to air or vice versa: but observa- ns of atmospheric electricity cast doubt on the stence of this part.

The main fact is that the earth's field above its surface is similar to that outside Gilbert's spherical loadstone; the intensity at distance r from the earth's centre varies as $1/r^3$. When r is equal to two earth radii, that is, 4000 miles above the earth's surface, the field is reduced to one-eighth its surface value. Hence it remains appreciable for thousands of miles above the earth. The tubes of force extend throughout, and far beyond, the atmosphere.

Solar Magnetism.

The sun's field is quite different in this respect. It is fortunately possible to measure its intensity at different depths within the solar atmosphere, for the composition varies with depth, and the Zeeman effect can be determined independently from spectral lines due to different atoms at different levels. In this way Hale and his colleagues discovered a rapid decrease of magnetic intensity with increasing height. The measured reduction (from 50 to 10 gauss for the polar intensity) is in the ratio 5 to 1, and extends over a linear distance of only about 50 km., according to Milne's theory of the solar atmosphere. If the sun's field, like the earth's, varied in intensity as $1/r^3$, this 5 to 1 reduction would extend over more than a million kilometres.

The intensity probably diminishes to values still lower than 10 gauss, though these cannot yet be measured on the sun. The rapid radial decrease of the field shows that few or no tubes of magnetic force can pass through the sun's atmosphere into outer space; they must lie nearly horizontally in the atmosphere. The difference between the solar and terrestrial fields is illustrated by the lines of force outside the full circles in Fig. 5.

The sun's field, like the earth's, is nearly symmetrical about an axis, which in the solar case is inclined at about 4° to the axis of rotation. The

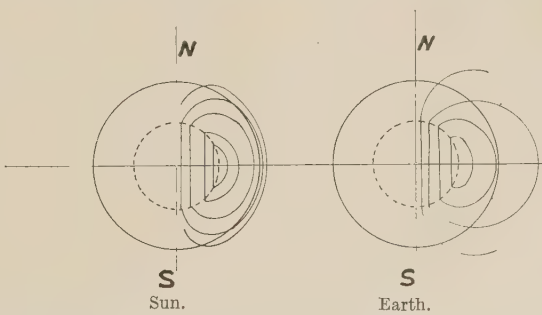


Fig. 5.—Lines of force in the solar and terrestrial magnetic fields: the curves inside the outer circles are merely conjectured.

magnetic polarity of the sun is the same, in relation to its direction of rotation, as for the earth—a fact of great theoretical interest. The earth's field, including its irregularities, rotates at the same speed as the nearly rigid earth, whereas the sun's field and magnetic axis rotate more slowly than the solar surface, the respective periods of rotation being about thirty-one days and twenty-six days.

The polar intensity of the earth's field is about $\frac{2}{3}$ of a gauss, while for the sun it is estimated to be 50 gauss; it may well be still greater lower down in the atmosphere, where the opacity of the gas prevents further observation.

In addition to the *general* field, there are very intense *local* magnetic fields in the sun's atmosphere, associated with sunspots: intensities of 3000 gauss are frequent; there is no corresponding terrestrial magnetic phenomenon. Sunspots commonly occur in pairs of opposite magnetic polarity; the two members of a pair generally lie along a line nearly parallel with the sun's equator. The polarity of the leading spots of pairs in one hemisphere (northern or southern) is the same as that of the following spots in the other hemisphere. The number of sunspots waxes and wanes in an eleven-year cycle: each cycle begins at sunspot minimum with the birth of spots in relatively high latitudes on the sun (about 30°); the spots are not of long continuance; as new spots appear and die away, their average latitude steadily decreases, both throughout the three or four years of increasing spot frequency, and in the subsequent seven or eight years after sunspot maximum, until the next epoch of minimum frequency is attained.

The cycle ends with the occasional appearance of spots near the solar equator; this continues for about a year after the beginning of a new cycle is marked by the recurrence of spots in high latitudes. All through the old cycle the leading spots in both hemispheres have a definite magnetic polarity, with few exceptions. In the new cycle the whole arrangement of polarities is reversed; the leading spots in both hemispheres have the polarity which in the preceding cycle characterised the leading spots in the other hemisphere. The complete cycle of sunspot change therefore extends over twenty-two years, and includes two maxima and two minima of sunspot frequency. A beautiful qualitative theory of this remarkable series of phenomena has been outlined by Bjerknes, and awaits quantitative development.

These are the main known facts regarding the solar and terrestrial magnetic fields, though in addition there are various transient fluctuations of the earth's magnetism, of small magnitude but of considerable theoretical interest.

Origin of the Magnetism of the Earth and Sun.

Many attempts have been made to provide a physical theory of the earth's magnetism, but with no definite success as yet. In Gilbert's time electromagnetism was unknown, and he was confident that the earth consists of magnetised matter, like his loadstones; he attributed the irregularities in the earth's field to the magnetic attraction of the continental and other inequalities of the earth's solid surface. A small, strongly magnetised, fraction of the globe, or a large part magnetised to a low intensity (0·1), would account for the field; but iron and other magnetic substances lose their magnetisability at critical temperatures which are attained at a small depth—20-30 km.—below the surface: there are various magnetic deposits in the layer above this depth, which are responsible for some notable local anomalies in the earth's field, but this layer seems quite insufficient to account for the main field. For a time it was hoped that the increase of pressure accompanying that of temperature as we go downward in the earth might raise the critical temperature, and so enable iron to remain magnetic at deeper levels; but recent experiments at the Geophysical Laboratory of the Carnegie Institution of Washington indicate that pressure has the opposite effect. The earth's magnetism must therefore be ascribed to some other cause, and the same is evidently necessary for the sun, owing to its gaseous state.

The next simplest hypothesis is that the fields are due to ordinary electric currents flowing inside the earth round the magnetic axis. Such internal currents will decay unless maintained by permanent electromotive forces; their free life is proportional to the conductivity and the square of the radius of the body, and for large bodies may be very long. In a globe of copper (at 0° C.) as large as the earth, the currents, as Lamb has shown, would take about 20 million years to decay in the ratio 10 to 1; while if the globe were as large as the sun, the time would be about two hundred thousand million years. I have recently estimated that the electrical conductivity at the centre of the sun is about 3×10^{-4}, half that of copper at ordinary temperatures, and that it decreases to about 10^{-8} just below the photosphere; large-scale electric currents in the sun would therefore die away at a rate imperceptible to us. The electrical conductivity of the earth is likely to be much less than that of copper, or even of iron (about 10^{-4}), at ordinary temperatures, because although iron possibly constitutes an important fraction of the core, its conductivity decreases considerably as the temperature rises; thus if *freely decaying* currents inside the earth are responsible for its magnetic field, their intensity in the remote past must have been immensely greater than now.

It must be left to future ages, by centuries of observation, to determine whether the fields of the sun and earth are decreasing; we cannot safely assume that the present rapid rate of diminution of the earth's field will continue. But there is no apparent reason why causes that could once generate such currents should altogether cease to operate, and the currents, if they exist, may be continuously maintained.

A possible mode of maintenance of internal electric currents has been suggested by Larmor; in the presence of the existing field, the necessary electromotive forces could be induced by an internal circulation having a component of its motion in the meridian planes, symmetrical about the axis and also with respect to the magnetic equator. Such a circulation might not only be able to *maintain* the electric current system and its magnetic fields: it might even build up the field from insignificant beginnings; and there is more than one known way in which the rotation could produce an initial field of very minute

ensity. The internal circulation, if once started, uld decay very slowly, owing, as Lamb has shown, the small influence of viscosity in large bodies; reover, it might be maintained against frictional ardation at the expense of the heat energy of body. In the sun, the motion of the mean nspot zone towards the equator during each ven-year cycle suggests the existence of a culation of the right type; and such a circula- n is invoked in Bjerknes' theory of sunspots, ich, whatever its difficulties, is the only one at has yet shown any capacity to explain remarkable collective properties of sunspots. have applied a rough numerical test to rmor's theory in the case of the sun, and the antities involved seem not unreasonable; there , however, some qualitative difficulties in the ory.

In the case of the earth, the existence of the posed circulation is entirely conjectural, though he underlying strata are slowly flowing equator- rds, and can exert a slight drag on the base of continental masses, it might fit in with and move a difficulty in theories of continental drift. rmor has remarked also that the secular changes the earth's magnetism might be simply accounted merely by change of the conducting channels the internal electric currents. The theory ems to me to have many attractive features, ough until it is further developed, especially on quantitative side, it must be viewed with erve, like other geophysical or astrophysical ories in their first qualitative stages. Edding- n has inferred from a theorem by von Zeipel at some kind of internal circulation must almost tainly arise in a rotating star; if it could be own that the circulation is likely to be of the sent type, Larmor's theory would gain further pport, and would add weight to the conjecture, de many years ago by Schuster and Kelvin, at magnetic polarity is a general property of ge rotating bodies.

A variety of other explanations of solar or ter- trial magnetism have been proposed, involving ation as an essential feature. Those based ely on known facts and established physical ys have all failed to explain more than a minute ction of the observed fields. Even the hypo- ses in which some liberty of speculation has en taken have in most cases involved contra- tions with observed facts of other kinds, which essitate their rejection. Any simple theory ich seeks to account for the observed intensities the fields of the earth and sun in terms of their own density, size, and angular velocity must also consistent with the observed failure of rotation, en at very considerable speeds, to produce gnetisation in non-magnetic bodies of small e in the laboratory; this proves to be a rather ingent limitation.

Among the theories which satisfy this condition l are based on some hitherto unrecognised damental property of matter, the most recon- e is that due to Swann. He modified the tromagnetic equations slightly, by the addition of small terms depending not only on v, the velocity of the electric charge, as in the classical theory, but also on $\dot{v}$ and $\ddot{v}$. His additional terms are such that no new effects arise merely through uniform *translation* of matter; that is, the equations remain invariant under the transformation of the restricted theory of relativity. The terms contain a factor, the form of which is chosen so that in the case of uniform *rotation* of neutral matter, with angular velocity ω, they imply the existence of a current density proportional to $\omega^4 r^3$, at distance r from the axis; this law of variation of the hypothetical current density was shown by Swann to be the only suitable simple law that will give magnetic fields of the right relative magnitude for the sun and the earth,[5] and a very small field for rotating bodies in the laboratory. Finally, by appropriate choice of a numerical constant involved in the new terms, the theory is made to fit the actual magnitudes of the solar and terrestrial fields. The whole procedure is elaborately *ad hoc*, and therefore somewhat unattractive, despite the skill with which the theory is developed. While the modified equations fulfil their intended purpose without appearing to introduce discrepancies with other observed facts, only one new consequence was inferred from them, namely, that small, rapidly rotating non-magnetic bodies should have a minute but just measurable field. Swann and Longacre have recently succeeded in testing this prediction, which is found to fail.

On the whole, it seems to me unlikely that cosmical magnetism has any fundamental significance in physics, involving, as in Swann's theory, small modifications in the general laws, which reveal themselves only in rotating bodies of great size. Any such hypothesis leads to a field symmetrical about the axis of rotation, whereas neither the sun's nor the earth's field is of this type; the obliquity of the magnetic to the rotational axis is about 4° for the sun, and about 12° for the earth. Thus the transverse component of the field, which a fundamental rotational theory cannot explain, amounts to a few per cent of the axial component. The secular variation of the earth's field is a further non-axial phenomenon of the same relative order of magnitude.

These asymmetrical features must be ascribed to causes which cannot be fundamental, and as they are not greatly inferior to the axial fields, it seems unnecessary to invoke fundamental hypotheses for the latter. Therefore in my opinion cosmical magnetism is probably only a secondary, though possibly widespread, phenomenon, and not a universal fundamental one like gravitation. If this be so, theories of cosmical magnetism must involve factors of an accidental character, not too rigorously determined *a priori*, in order that they may account for the varied secondary features of the solar and terrestrial magnetic fields. In this respect Larmor's semi-hydrodynamical theory seems preferable to hypotheses like Swann's.

[5] Owing to the uncertainty as to the true maximum intensity of the magnetic field of the sun, it is unsafe to attach much importance to the observed ratio of the solar and terrestrial intensities.

The Electrical Conductivity within the Earth.

Though the cause of the earth's magnetism and its secular variation is still uncertain, the study of these phenomena is likely in time to add materially to our knowledge of the earth's interior. At present our knowledge of this region is derived mainly from quite different lines of evidence; every fresh sidelight on this *terra incognita* is worth the most careful attention. The secular variation suggests that, despite the mechanical stability of the earth, fairly rapid changes are proceeding within it, and that the interior is much more mobile than the outer layers: when the variation has been observed over a longer period, detailed inferences as to the nature of the internal changes should become possible. Already, however, terrestrial magnetism has provided one definite fact regarding the earth's interior, which could scarcely have been obtained otherwise; hitherto no use has been made of it in theories of the constitution of the earth, and perhaps laboratory experiments are required before this will be feasible, but the fact must sooner or later be taken into account.

If a conducting body be placed in a varying magnetic field, electric currents will be induced in it; the more rapid the variation of the field, the greater the current-density near the surface of the body, and the thinner the layer wherein the currents flow. The currents shield the interior from the varying magnetic field by superposing an opposing field of their own, while outside the body their field strengthens certain components of the original field. If the body is spherical, by harmonic analysis of the surface field we can separately evaluate the parts of external and internal origin; the method, due to Gauss, was first applied for this purpose by Schuster, to the *daily variation* of the earth's magnetic field. It is found that the daily-varying part of the field is mainly of external origin, but there is a smaller part of internal origin; Schuster ascribed this to currents induced in the earth by the outer varying field. In conjunction with Lamb, he showed that the ratio of the intensities of the external and internal parts of the field, together with the difference of phase between them, are inconsistent with the assumption that the earth is a uniformly conducting sphere. The magnetic data show, in fact, that the effective conducting sphere must be smaller. The depth of its surface is estimated to be about 200 miles, and its specific electrical resistance ρ is about 3×10^{12} e.m.u., or roughly 300 million times that of iron at ordinary temperature; naturally there is no reason to suppose that the resistivity undergoes a quite sudden transition at this depth. The resistivity 3×10^{12} is, however, 400 to 4000 times less than that of dry earth or rock, of which the outermost layer is formed, so that a great change of composition or state must occur at about 200 miles depth. There appears to be no other geophysical evidence of a rapid change in properties at this level inside the earth.

Even the outermost layer of the earth is sufficiently conducting for measurable currents to flow in it, but they are too weak to shield the conducting core from fields which vary with a period of the order of a day. During magnetic disturbances much quicker variations occur, and the measured earth currents, which are far stronger than usual, may have an appreciable shielding effect. The *oceans* are more highly conducting ($\rho = 2 \times 10^{10}$) than either rock or the conducting core, and if they covered the globe uniformly to a depth of half a mile the currents induced in them by the daily varying field would shield the interior almost completely, and the existence of the conducting core would not be disclosed; actually, the oceans are so broken up by land masses that the shielding effect of the currents induced in them is greatly reduced.

If the core is of *uniform* resistivity 3×10^{12}, the currents induced in it by the daily variation of the earth's field will decrease downwards until at a depth of about one-tenth its radius they are very small, and the outer varying field is almost annulled. The conductivity below this depth is therefore of no significance in relation to the daily magnetic variation, and we remain in ignorance of it. Our existing knowledge refers to a total depth of about 600 miles, or less if the conductivity of the core increases downwards; this outer layer shields the interior from outer varying magnetic fields of period one day or less. The conductivity of the deeper interior could be explored only by means of fields—which must be on a large scale, comparable with the earth's size—that vary much more slowly. There is an annual variation of the earth's field, probably of external origin, but it is small and not well determined: in time it may be used to ascertain the conductivity at lower levels, but at present this is not possible.

If the whole earth below 200 miles depth had the uniform resistance 3×10^{12}, freely decaying currents within it would be reduced in the ratio 10 to 1 in about five days: hence any currents producing the main field and the secular variation would have to be continuously maintained; moreover, the secular variation would be scarcely affected by self-induction, because its changes are periodic, if at all, only in a far longer interval, of hundreds of years. It may be, however, that the conductivity goes on increasing towards the earth's centre, the increasingly metallic character outweighing the opposing influence of rising temperature, and possibly also pressure, on the conductivity.

Fig. 6 shows in crude outline the estimated electrical resistance of different strata in the earth, and of the Heaviside layer in our atmosphere. It also shows the theoretical estimates I have made for different depths within the sun, which at the centre is probably nearly as good a conductor as copper is at ordinary temperatures.

Radial Limitation of the Sun's Magnetic Field.

Leaving terrestrial problems, let us again consider the sun's magnetic field. It has been seen that the tubes of magnetic force in the sun's atmo-

here lie nearly horizontal, and do not spread out to space as do those of the earth. Since the tubes are necessarily closed, they must complete their course inside the sun.

Hence the northward tubes observed in the sun's atmosphere must turn and become southward in the interior. Near the surface the force is northward and increasing downwards; since at some greater depth it is reversed in sign, it must first attain a maximum northward intensity and then decrease, become zero, and increase once more with the opposite sign. The depth and magnitude of the maximum northward intensity are unknown, and *a fortiori* the depth at which the force is reversed; if we knew these quantities, we could calculate the mean intensity of southward force below this depth, since as many tubes go northward as return southward.

By considering a line-integral of the magnetic force round a contour, in any meridian plane, formed of horizontal and radial lines, it appears by Ampère's rule that electrical currents must be flowing round the sun's atmosphere, along the circles of latitude, in the easterly direction as reckoned by an observer situated on the sun. The eastward electric currents extend approximately down to the depth of maximum northward force, below which the currents are westward—unless, which is perhaps unlikely, the field and the currents are reversed more than once inside the sun.

The *westward* currents are the primary cause of the sun's magnetic field, and their origin is the fundamental problem of solar magnetism. I have already described the theory, due to Larmor, which seems to give a possible explanation both of their origin and also of the earth's field. The second major problem of solar magnetism is afforded by the restriction of the field within the solar atmosphere. The immediate cause is the eastward current-system, which has the same effect as a shell of highly permeable magnetic matter enclosing the sun; it superposes an additional magnetic field which, in the external space, neutralises the primary field, while intensifying this field within the layer. The eastward currents cannot be the main cause of the sun's field: if they alone were present, their field would spread outwards into space.

It appears possible to account for these eastward currents in a simple manner by a theory which also enables the magnetic intensity to be used to calculate the pressure in the solar atmosphere, and gives a value agreeing well with that deduced in a totally different way by Milne.

The solar atmosphere is so hot that most of the atoms in it are ionised. The ions and electrons are subject to an electromagnetic force due to their motion in the magnetic field, and also to vertical gravitational and electrostatic forces. The electrostatic force is due to the tendency of the very light electrons to rise towards the top of the atmosphere. This tendency is almost entirely prevented, but a very slight separation occurs which suffices to equalise the downward forces on the ions and electrons; the ions are half supported by the electrostatic field, while the electrons are held down by it with a force equal to half the ionic mass.

Apart from these vertical forces, each of the ions and electrons would spiral round some line of magnetic force, the average motion therefore being to the north or south. Since the ions and electrons move equally to north and south, no average

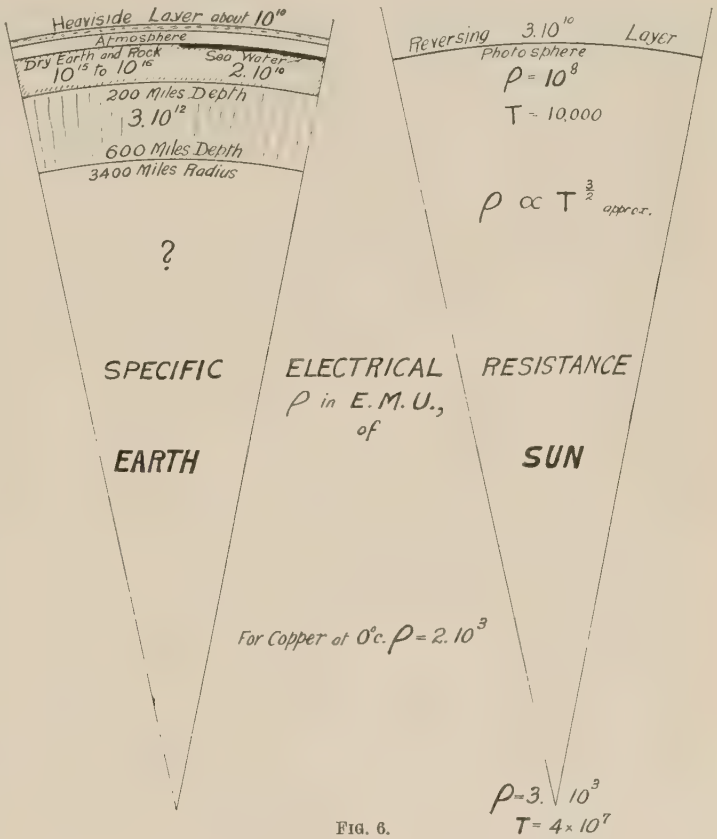

FIG. 6.

current results, and this motion along the magnetic field can for simplicity be ignored. The vertical force produces a constant downward acceleration of the free charged particle, but the magnetic field continually deflects the velocity round the lines of force, without affecting its magnitude. While a particle is moving downward its velocity is increasing, owing to the vertical force, but the magnetic field rotates the velocity, so that the motion becomes first horizontal and then upward again; during the upward motion the velocity is diminished by the vertical force, and turned so that the motion again becomes horizontal and then downward. The horizontal velocity at the top of the path is less than at the bottom, and the effect of the vertical force is to impart an average horizontal motion in the direction of the velocity at the lowest point of the path; there is no average vertical

velocity or acceleration. The motion, projected on the plane normal to the magnetic force (the vertical plane in the east-west direction), from being circular becomes trochoidal, the average velocity being to east or west. The motion is westerly for the electrons, which, viewed from the south, spiral round the field in the clockwise direction; for the positive ions, the motion of which is anti-clockwise, it is easterly. In either case the motion is equivalent to an easterly current, such as must exist in the sun's atmosphere, where the magnetic intensity is decreasing upwards; I have termed this current a 'drift' current, since it is not due to an electromotive force in its own direction, but to a transverse force. A mechanical analogy of this drift is well known. A rough sphere placed upon an inclined plane which rotates uniformly about some axis normal to itself acquires no mean motion down the plane, but describes a trochoidal path with its mean motion horizontal, transverse to the component of gravity down the plane.

Such drift currents will have free play only if the gas is sufficiently rare for the particles to execute many turns in their trochoidal paths between collisions with one another. This requires that the radius of the spiral is small compared with the mean free path of the particle. The mean free path is much the same for the ions and electrons, but the spiral radii are very different, being approximately in the ratio of the square roots of their masses; thus the electrons may be free to spiral and to drift when the ions cannot do so; this appears to be the case in the sun's reversing layer, where the magnetic field is observed. A simple calculation then shows that in this region $dH^2/dp = 8\pi$, where H denotes the magnetic intensity and p the electron pressure. The distance within which the decrease occurs can also be calculated, and proves to be only about 20 km.

It is not possible at present to infer theoretically how far the magnetic field is likely to *increase* as we go downwards into the photosphere; the increase is limited by the fact that the mean free path decreases downwards in the ratio $1/p$, while the 'spiral-radius' of the electronic paths decreases as $1/H$ or, approximately, as $1/p^{\frac{1}{2}}$. Hence the mean free path is reduced the more rapidly, and when it becomes approximately equal to the spiral-radius, the electronic drift current will cease. This must occur within 100 km. of the photosphere, but the calculation of the exact level is rendered difficult by the indefiniteness of the mean free path in the case of particles which are not rigid spheres, but behave like point centres of force, particularly when the law of force is the inverse square law of electrostatic action.

In these calculations no account has been taken of the influence of the magnetic field on the mechanical equilibrium of the sun's atmosphere. The field partly supports the free charges, and an atmospheric layer of given total mass will therefore be more spread out, in the vertical direction, than if the field were absent. When this effect is allowed for, the formula $dH^2/dp = 8\pi$ is modified, but the drift-current theory of the radial limitation of the field is not essentially changed.

Terrestrial Drift Currents and other Electromagnetic Phenomena.

Similar effects must occur in the earth's atmosphere, which is ionised at high levels by solar radiations. Eastward drift currents will flow at heights where the mean free path is larger than, or comparable with, the spiral-radius of ions and electrons; in the earth's field, at the equator, the spiral-radius is about 2 cm. for an electron, and 5 metres for an ionised oxygen or nitrogen molecule; consequently *electronic* drift currents will occur at heights above about 70 km., and *ionic* drift currents above about 150 km. But the number of electrons and ions is much less than would be required to enable the drift currents to shield the outer space from the earth's magnetic field; less than 5 per cent of the tubes of force crossing the earth's surface are confined within the atmosphere by the drift currents. This estimate is derived from the spherical harmonic analysis of the earth's field, which shows that only about 3 per cent of the surface intensity is due to overhead currents; from this it is possible to infer that there are less than 10^{16} ions per sq. cm. column of atmosphere, above a height of 150 km. An independent check on this estimated upper limit will become available before long from measurements of the ionic density at different heights, by means of the reflection of wireless waves by the upper atmosphere.

Besides these major problems, there are others of equal theoretical interest, which relate to smaller or local components of the solar and terrestrial magnetic fields. The solar corona appears to indicate the existence of a magnetic field, probably of low intensity, above the chromosphere. Among the further phenomena of terrestrial magnetism, the chief are the solar and lunar daily variations, and magnetic storms with their associated auroræ; these originate above the earth's surface, in or outside our atmosphere. They have important connexions with solar physics, and also with so practical a matter as radio propagation; in recent years the electrical exploration of the upper atmosphere by beams of radio waves has lent powerful aid in their investigation. During the past century some progress has been made towards a physical theory of these changes, but much more remains to be done.

The problems involved, like those relating to the main field of the earth, are of rather long standing; they probably depend only on the working of already known laws, in ways not yet recognised, and therefore they do not possess the importance that attaches to such problems as those of atomic physics; nevertheless, they have much fascination and interest, and until they are solved they constitute a challenge to the theoretical physicist; in time the challenge will be met, but that time may be still distant.

bits auxiliary to local industry come from the h. The Cambridge Scientific Instrument Com- supplies its pyrometers to brick and tile ks.

ne natural advantages already described are to those who wish to start new industries. In nicals, iron, engineering, and shipbuilding it be less easy to begin on a small scale than it a century ago with less powerful competitors. the district seems a good one for new inventions ating new patents. Coal, gas, and electric ent are available as power. There is a net- of railways and motor-bus routes. There is rabundant labour already somewhat housed. ventures will be welcomed by a population tant to emigrate although ill-advised in leav- nitiative to others. The large-scale models of Tyne Improvement and Tees Conservancy missioners will help in the choice of sites for ories; the L.N.E.R. is also ready to advise. stries scarcely yet acclimatised include the ing of agricultural machinery and motor- es.

his exhibition goes much further than earlier mpts to restore confidence by talking con- ce. The goods are ready. The method of rtisement is being pushed for all it is worth. d has gone out through the world in English, ch, German, and Spanish. There will be con- ces of advertisers, of international foundry- and notably the Baltic and White Sea Con- ce. The success of the exhibition is to be ed by orders for ships, bridges, and machinery er than by gate-money on bank holidays. The od of advertisement may have its limits; it lead to private profit at the price of public e. The exhibition and its catalogues are mples of economy in advertisement by co- ation, a stepping-stone towards the trans- ation of advertisement into a public service. relation of the co-operative wholesale society e co-operative stores in the pit-villages tends rds the tied-house principle, eliminating the for advertisement. Even if the method of rtisement cannot command success, it is doing it can to deserve it.

much for the microcosm in which the scientific orer will find himself if he comes to make the oition a starting-point for some survey of the n-east of England. The causes of present distress been incompletely advertised. It is not only st-War slump in munitions. For fifty years side has been content to make high profits and wages whilst specialising in the production of tions. Nemesis has come home with a venge-

There is a heavy load of the disabled to rried; the education of the blind is the only al educational exhibit. The unemployed in- the less employable and the less versatile. ership has been decimated. Unemployment name for a scarcity of employers is a view not nasised by labour leaders. Labour propaganda ooked numbly to the State. During the coal page of 1926 it may have seemed right to say on and hope. In retrospect, emigration would have been wiser. Many of the inland coal mines, for example near Bishop Auckland, are worked out, though the deeper mines near the Durham coast are at work. It seems a tragic mistake that emigration has been discouraged by those to whom the miners look for advice. The Lord Mayor's Fund has been a gesture of generosity; it only makes idleness a trifle less intolerable.

Various tempers of mind—religious, philanthropic, political—have already been applied to our problems without yielding complete solutions. Before prescribing panaceas we need the whole truth. It is whispered that in the past it has been far too easy to make money on Tyneside. This view is endorsed by Dr. H. A. Mess in "Industrial Tyneside". Traditional industries have scarcely thought it necessary to bring in scientific advice; even to-day a chemist is felt to be out of place on a board of directors. Some industries requiring high intelligence have left the district; electric lamps and aniline dyes are examples. So far there is too little response to the offers of the National Institute of Industrial Psychology to help in selecting personnel and arranging work. There is a reluctance to climb down from high prices, high profits, and high wages.

What is to be done if the method of advertisement fails? The restoration of the general prosperity of our neighbours beyond the North Sea is urgent. A voluntary Interessengemeinschaft between chemical firms, already in the imperial stage of evolution, would be a safeguard against future misuse of nitrates and by-products. Armstrong College, fed by scholarships through the secondary schools, is preparing the next generation of employers. Even if the rest of England hesitates there seems a fair case for asking for a prior and immediate application of the Hadow Report raising the school age by one year in the colliery areas. For the next or prevocational year up to age sixteen the teachers are still to be discovered and trained. A great development of junior technical schools is desirable until every young person has at least one and preferably several ways of earning a living. It is proving very difficult to reconvert townsfolk into agriculturalists. There is a Migration Training Hostel for boys in Walker, and a Domestic Training Hostel for girls in Benton, but what are these among so many?

Emigration is probably urgent and almost without waiting to ask whether the new countries will speak Russian, Spanish, or Dutch. When customers are invited from all nations it seems absurd to limit emigration to the British Empire. The nations emigrating to America have faced a new language and an alien culture. A generation ago the Irish had to leave home: a like fate is before our boys and girls. The best ages for emigrating are said to be sixteen to twenty-three, and the best form of assistance education and training whilst still near home. Some sort of vocational guidance might be offered to every one, followed by technical training according to capacity. The boys and girls in their school caps and badges are seen eagerly examining the exhibits; to them the exhibition is a means of education.

HUGH RICHARDSON.

South Africa Meeting of the British Association.

THE meeting opens on Monday, July 22, and for the convenience of members who arrive in Cape Town before this date, offices and reception rooms are being opened in the old University Buildings, Queen Victoria Street, on July 15. Business in connexion with railway travel and with local excursions will be transacted at these offices. The meetings of the sections will be held in the new University buildings at Groote Schuur, Rondebosch, which can be reached by rail, tram, or bus from Cape Town.

Local excursions to points of interest and beauty in the Cape Peninsula are being arranged, and the Royal Observatory will be open for inspection. It is hoped that the cable railway to the top of Table Mountain will be ready for traffic, thus facilitating the ascent. For visitors interested in geology, excursions are being arranged for an inspection of the granite-slate contact at Sea Point and to Chapman's Peak, where a general idea of the structure of the Cape Peninsula can be obtained. On the way from Cape Town to Kimberley, geologists will have an opportunity of inspecting the Folded Mountain Belt, the Cape System, and the Karroo System; at Kimberley they will be able to inspect the diamond mines and the glacial phenomena of the Dwyka Series. Thereafter, on arrival at Johannesburg and Pretoria, they may link up with the International Geological Congress.

It is anticipated that about 550 visitors from overseas will attend the meeting, and the transportation of these, together with a number of local members, by rail from Cape Town to Johannesburg in a limited time will tax the resources of the railway, which runs for most of the way as a single track and has many steep gradients. A special train for local members will leave Cape Town on Saturday, July 27; two special trains for visiting members will leave Cape Town on the morning of Sunday, July 28, and two more on the morning of Monday, July 29. Each of the parties of visiting members will spend about twelve hours at Kimberley, and will then proceed to Johannesburg, where they will arrive on July 30 and July 31.

At Kimberley the diamond mines of the De Beers Consolidated Mines will be visited. It is anticipated that practically all of the visitors will desire to see the workings of a gold mine. The underground workings of the mines can only be visited during the early part of the day, as all underground passages must be cleared for blasting operations during the afternoon. The visitors will be taken in small parties to various mines; for those specially interested a small party is being organised to visit one of the deep, hot mines.

Astronomers will be afforded an opportunity to visit the Union Observatory and the Yale telescope, which is housed in the grounds of the University of the Witwatersrand.

The meetings of the sections in Johannesburg will be held in the University of the Witwatersrand, and the premises of the Associated Scientific and Technical Societies of South Africa, in the centre of the town, will be available for the visiting members.

Visits have been arranged to the Rand Gold Refinery, to the explosives factory of African Explosives and Industries, Ltd., at Modderfontein and to the Royal Mint at Pretoria. The large air compressors of the Victoria Falls Power Company at Rosherville will be of interest to engineers, as will also be the Central Electric Power Station at Witbank. The Rand Water Board has arranged a visit to the barrage across the Vaal River and to the waterworks at Vereeniging. For anthropologists visits can be arranged to the Leslie collection of stone implements at Vereeniging, to stone circles at Aasvogel Kop and at Heidelberg, to the native stads at Rustenburg, and to stone huts at Vechtkop (Heilbron, O.F.S.). Several botanical excursions are being organised, as also are visits to institutions of an educational character. The South African Institute for Medical Research at Johannesburg and the Government Veterinary Research Laboratories at Onderstepoort, near Pretoria, will be open for inspection. On the morning of Sunday, Aug. 4, exhibitions of native war dances will be given. A display of tribal types is being organised by the Witwatersrand Native Labour Association, which should prove to be a particular attraction to all overseas visitors. From Pretoria a visit will be made to the Premier Diamond Mine.

Under the auspices of the South African Association, a handbook dealing with South Africa from the travel and scientific aspect has been prepared for presentation to visiting overseas members. The book contains a foreword by His Excellency the Earl of Athlone, Governor-General, and chapters on travel in South Africa, Southern Rhodesia, government, education, geology, gold, diamonds, other minerals, agriculture, vegetation, fauna, astronomy, anthropology, medical research, commerce, and game reserves. The book will be available to members at Cape Town, and the information in it should add to the interest of the visit to South Africa. Portfolios of etchings will be presented to overseas members at Cape Town; the etchings depict typical South African scenery and architecture (chiefly in the neighbourhood of Cape Town), and will form a not uninteresting souvenir.

At the opening session on Monday, July 22, at Cape Town, members of the British Association will be welcomed to South Africa by His Excellency the Governor-General. At this session the South Africa Research Medal (founded in commemoration of the visit of the British Association to South Africa in 1905) will be presented to Dr. Robert Broom for his archæological and anthropological researches.

The South African Association has extended invitations to a number of scientific workers to attend the meeting in South Africa as guests, and Prof. O. Abel, Sir J. C. Bose, M. l'Abbé Breuil, Prof. C. Dragoni, Prof. A. S. Eddington, Prof. A. Hitchcock, Prof. G. A. F. Molengraaf, Dr. C.

rs, Sir John Russell, and Dr. W. de Sitter are cted to be present.

ne evening at Cape Town will be devoted to a ission on science and industry, which will be inued on another evening at Johannesburg.

ne meeting concludes officially at Johannesburg ug. 3 ; thereafter most of the visitors will proceed on sight-seeing tours, and doubtless many of them will take the opportunity of visiting the Victoria Falls. One party will assemble at Durban towards the end of August, and a semi-official session will be held there ; this party will be joined by the president, Sir Thomas Holland, who will give a special address at Durban.

News and Views.

N important step in the development of the Waite itute for Agricultural Research, South Australia, taken when the John Melrose Laboratory was ially opened at the end of April. The Institute established some years ago as the result of a gift the late Mr. Peter Waite to the University of laide for the purpose of furthering education and arch in agriculture and allied subjects. The wment comprises the Urrbrae, Claremont, and nerby Estates lying on the scarp of the Adelaide ills within four miles of the city and consisting early 300 acres. In addition there is a trust fund 58,450. Of recent years considerable assistance been forthcoming from the State Government, ire Marketing Board, the Council for Scientific Industrial Research, Imperial Chemical Industries, , and the Commonwealth Bank of Australia. need for increased laboratory accommodation been acutely felt, and, mainly through the gener- of Sir John Melrose in providing the sum of 000, a wing has been completed of what will in constitute a large block of laboratory buildings.

HE Melrose Laboratory at the Waite Institute ains two main floors, the ground floor being ted to administrative and botanical work, and the floor mainly to chemical work, but with provision for entomology. The entire content of the build- s approximately 274,000 cubic feet and the total space 14,700 square feet. Quite possibly further nsions may soon prove necessary, as it is under- d that the Council for Scientific and Industrial earch and the University of Adelaide are dis- ing a project for establishing jointly at the itute a Division of Soils Research. The need for ve of the kind has been very apparent in Australia ome time, and there can be little doubt that its blishment at the Waite Institute would be a wise e, as this Institute is rapidly becoming one of the t important centres of agricultural research in the mmonwealth.

ESSRS. SOTHERAN, LTD., booksellers, Strand and adilly, have in their hands and are proposing to *en bloc* a collection of some eight hundred and y books which undoubtedly formed a part of a ry brought together by Sir Isaac Newton. It been known to a past generation that at Newton's h a large mass of papers, annotated copies of his and other authors' works, and an extensive cor- ondence with English and foreign mathematicians, ained with Mr. Conduitt and his wife. Ultimately e of this series which related to science were pre- ed to the University of Cambridge in 1872 by the Earl of Portsmouth, and were reported on in 1888 over the signatures of such authorities as H. R. Luard, G. G. Stokes, J. C. Adams, and G. D. Liveing.

THE works that actually constituted Newton's library occupy, however, a different niche in history, unrecorded as an entity by his biographers. One may, perhaps, conjecture that the volumes were left intact at the house in St. Martin's Street, Leicester Fields (occupied for so long by the philosopher), and not removed on his change of quarters, through ill-health, to Kensington, where he died within a brief space, in 1727 ; certainly the old residence was still on the rate books of his former parish at that date. Twenty books in the above collection bear Newton's autograph ; four are dated 1661 ; whilst eighty-three carry, here and there, notes in his handwriting. The first and second editions of the "Principia" (with numerous corrections) are prime items of interest in the set. Some of the books have presentation inscriptions to Newton by their authors ; others are finely bound in contemporary morocco. A Latin-Greek Dictionary (1650) with autograph, has the date Mar. 29, 1661, presumed to be the earliest known Newtonian signature, in any case, written shortly before he entered Trinity College, Cambridge.

FROM a reprint of the correspondence between Isaac Newton and Robert Hooke during the years 1679–1680, published in chapter viii. of Rouse Ball's "Essay on Newton's Principia", pp. 138-153 (Macmillan), 1893, two letters were missing. These letters "are known to have been written, but they have never been published, and it is possible that no copies of them are now extant". The correspondence dealt with the question of the path of a falling body, "moved circularly by the diurnal motion of the earth, and perpendicularly by the power of gravity". The first of the missing letters was read to the Royal Society on Dec. 11, 1679, two days after Hooke sent it to Newton. The reply from Newton, dated Trin. Coll., Dec. 13, 1679, and addressed : "For Mr. Robert Hooke, at his Lodgings in Gresham College in London," was discovered in a collection of autographs, sold in 1904 by Messrs. Sotheby to the British Museum. Thanks to the courtesy of the Keeper of the Manuscripts, Dr. Jean Pelseneer of Brussels has been permitted to print (*Isis*, xii. No. 38, May 1929) the hitherto unpublished letter. The 'find' is not only interesting in itself for the part that it played in the history of the genesis of the "Principia", but also as an earnest of more to come. Thanks to the assistance he has received from the Belgian National Fund for Scientific Research, Dr. Pelseneer hopes to bring before the public further

documents by Newton which have not yet been published. We may add that in the *Isis* article of 16 pp. he gives his readers an excellent summary of the correspondence, with the circumstances in which it was written.

THE Meteorological Office, Air Ministry, has issued a special report upon the shortage of rain over the British Isles during the period of six months including December last and the first five months of the present year. Except to certain sections of the community who for special reasons are intimately concerned with the total amount of rain during such a long period, as for example farmers and engineers who deal with water-supply, a shortage of the kind under consideration may easily pass unnoticed. This is particularly the case when the dry spell has been marked by not infrequent periods of dull, windy and wet weather during which appearances have been misleading and the amount measured in a rain-gauge has been trifling. The official report is accompanied by a map showing the rainfall for the six months expressed as a percentage of the normal fall for the same period. This map reveals the fact that only the coastal districts of the south of Ireland and the extreme south-west of England show any considerable areas where there has not been a deficiency, and that over a considerable part of north-west Ireland, western Scotland, Wales and England, there has been less than half the usual quantity.

AMONG places mentioned in the report which show particularly low percentage amounts of rainfall are Llangurig (Montgomery), with 30 per cent; Rhyader (Radnor), with 35 per cent; Margate, 36 per cent; Fort Augustus (Inverness), 38 per cent, and Aspatria (Cumberland), 39 per cent. At Margate the remarkably low total fall of slightly less than $2\frac{3}{4}$ inches was measured. It is interesting to note that the last month of the series—May—was the only one in which the British Isles as a whole showed a slight excess rainfall above the normal, and there seemed to be some hope that the tendency for drought had come to an end. June has, however, showed some notable dry periods, and when the figures for that month are collected and the period of seven months from last December is considered, the general shortage will probably stand out as one of the most notable, if not the most notable, of any dry period of that length in Great Britain since accurate rainfall measurement began.

THE approaching visit to South Africa of the British Association has undoubtedly stimulated interest in its many archæological and ethnological problems, not least perhaps those which centre in the prehistoric stone buildings, of which the greatest and best known is Great Zimbabwe. In addition to the expedition, of which Miss Caton-Thompson is the leader, sent out by the British Association itself, and the independent investigations being carried out under permit of the Rhodesian authorities by Dr. Leo Frobenius, an Italian expedition is in the field. It has been sent out under the auspices of the Royal University of Florence. One of the members, Dr. Lidio Cipriani, professor of ethnology in the University of Florenc is reported in the *Times* of June 21 to have arrive at the conclusion that the Zimbabwe collective are a native product, the work of an African peop without any foreign influence. It is to be hoped th Dr. Cipriani may have an opportunity of laying h views before the Association. Dr. Cipriani is al reported to have discovered some Bushmen paintin of exceptional significance. They exhibit the featu of superposition, a painting of an Arab typical dressed having been found under a picture of a Bus man fighting Bantus. This, needless to say, confirm the relatively late date of the Bushman painting some of which indeed are known to be quite moder These paintings were found in the Marandellas distric An engraving found at Mazabuka is said to be lik nothing found elsewhere in Africa and to give certai indication of prehistoric man. The description, hov ever, is too vague to give any clear idea of i character.

As was announced in our issue of June 22, p. 95 by arrangement with the Air Ministry and Messr Wireless Pictures (1928) Ltd., synoptic weather chart are being broadcast from the Daventry Station (5 XX of the British Broadcasting Corporation every Tue day and Thursday between 2 P.M. and 2.25 P.M. Re ports of the reception of these charts on a Fultograp from as many different places as possible will be c the greatest value to the experimenters. Any pos sessor of a Fultograph can obtain a supply of prepare paper and envelopes and also full particulars of th reports required by writing to Wireless Pictures (1928 Ltd., Dorland House, 14-16 Regent Street, Londo We hope that the results will demonstrate that it i possible to send in a few minutes from a central statio to all parts of the country, and to airships and aero planes in flight, weather charts and forecasts. It wi be of the greatest value for pilots to see at a glance th state of the weather in the districts to which they ar flying.

THE history of Danish broadcasting is a notabl example of the wisdom of State encouragement o amateur effort. In the *Wireless World* for June 1 a good account is given by P. O. Langballe of th rise of broadcasting in Denmark. In 1922 it cam into existence almost accidentally. Government test were being made with the view of establishing radi telephony between the mainland and the Island o Bornholm, using a Poulsen continuous wave trans mitter. During these tests several amateurs wer surprised to hear something that sounded like th scratching music made by an old gramophone. Whe regular reception was established, it was foun impossible to prevent 'listening in'. Private trans mission, however, was forbidden. This led to th formation of the Danish radio club, the members o which were anxious to secure the same privileges a radio enthusiasts in other countries. A moder valve transmitter was erected at a station just outsid Copenhagen. Although the plant was supplied b the State, its operation and maintenance were en trusted to the radio club. This arrangement provin

uccess, no difficulty was experienced in getting mission to erect a broadcasting station in Copen- en itself, funds being provided by the State and ew private subscribers. The club operated this station at first, but as the programmes became porate and the expenses heavy, the State assumed trol and a radio bill was passed taxing all listeners. tax is now a uniform one of ten crowns per annum. first relay stations were fitted on the passenger mers between Copenhagen and Jutland. They ked up the Copenhagen programmes and trans- ted them. A high power station has now been lt at Kalundborg on the western coast of Seeland. ratio of licensed listeners to the total population reater in Denmark than in any other country in world.

AN expedition under the auspices of the German vernment to study the ice-sheet of Greenland is ng undertaken this year. Prof. A. Wegener, who had previous experience in Greenland, will be in rge. This year's work will be by way of prepara- for the main undertaking next year. According the *Geographical Journal* for June, three stations be established in the same latitude but at wide rvals. The first will be about 12 miles within ice-sheet in the Umanak district. The second be in the central part of the ice-sheet, and the d will be on Scoresby Sound. Wintering parties inhabit all the stations and take the temperature the ice at different levels. Radio and weather casting stations will be established at the three ions. It is proposed to use motor sledges as well logs and Icelandic ponies in transport.

N his address to the Royal Geographical Society at annual general meeting on June 24, Sir Charles se referred to the growing value and importance ir surveys. Some attempts at aerial photography e made last century, but nothing practical in aerial vey was achieved until the aeroplane supplanted balloon as a means of air transport. It was during War that air photography became a recognised hod of survey. Sir Charles Close went on to give e account of air surveys that have been made or in process of completion. Perhaps the out- nding example of aerial survey is that of the diffi- country in Brazilian Guayana along the Rio ro, Rio Branco, and Rio Parima. The whole is ered with dense forest, but about 12,000 square es were photographed in 174 hours. Then the ail was fitted into a framework of astronomically d positions which were made along the rivers. As uick means of survey in new countries, aerial photo- phy has been used in Northern Rhodesia, Iraq, ma, and the Rio de Janeiro district in South erica, the Malay States and elsewhere. Rapid rovements in the cartography of many of the less wn parts of the world are thus rendered possible.

A LARGE earthquake was recorded at Kew Observa- y on June 27. The first tremors reached the ervatory at 13 hr. 1 m. 38 sec. G.M.T. The epi- tre is estimated to have been 7500 miles away, but the initial impulse was too small to be any indication of the bearing.

MR. L. BELLINGHAM, of Messrs. Bellingham and Stanley Ltd., 71 Hornsey Rise, N.19, reminds us that the electrification of omnibuses described by Prof. C. V. Boys in our issue of June 29 was pointed out by him in NATURE of Sept. 10, 1927, p. 367. He believes the charge is the result of the friction on the brake drums rather than the rolling of the tyres on the asphalt, because he has noticed it particularly on the buses descending Crouch Hill on the portion of the road which is paved with granite setts. These small electric shocks are well known to the conductors, but they attribute it to a slight leakage from the magneto.

IT is probably known to our astronomical readers that for the measurement of positions and areas of sunspots a collection of solar photographs for each day of the year is made at Greenwich with the co-operation of the observatories of the Cape and Kodaikanal. In most cases there are two or more photographs for each day. One complete set is preserved at the Royal Observatory, and we are informed that arrangements have recently been made for a duplicate set to be stored at the Science Museum, South Kensington. This has the great advantage of housing two complete sets at different places, in case of accident; also the set at the Science Museum is easily accessible to students of astronomy and magnetism who may wish to consult the negatives.

AT the meeting of the Geological Society held on June 26, the following foreign members were elected: Prof. Charles Schuchert, of Yale University, New Haven, Connecticut; Prof. Pierre Termier, Directeur des Services de la Carte Géologique de France, Paris; Dr. Edward Oscar Ulrich, U.S. Geological Survey, Washington, D.C.; and Dr. Thomas Wayland Vaughan, Director of the Scripps Institution of Oceanography, University of California. Foreign Correspondents were also elected as follow: Prof. Othenio Abel, of Vienna; Dr. Clarence N. Fenner, of Washington, D.C.; Prof. Olaf Holtedahl, of Oslo, Norway; Dr. Rudolf Staub, of Berne, Switzerland; Dr. V. K. Ting, of Peking, China; and Prof. Carl Wiman, of Upsala, Sweden.

IN the Calendar of Patent Records which appeared in the issue of NATURE for June 1, the entry relating to the invention of vaseline referred to the provision of the law which denies registration as a trade-mark to a commonly-used descriptive word, and cited 'vaseline' as a case to which this provision had been applied by the British Courts. Mr. R. F. Kennedy, 12 Church Street, Liverpool, has pointed out, however, that although the lower Court ordered the removal of the mark 'vaseline' from the register on the grounds stated, this decision was afterwards reversed by the Court of Appeal, and the registration of the word as a trade-mark, first effected in 1877, remained in force.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A scientific officer and a junior scientific officer on

the Air Ministry Scientific Research Staff, primarily for duty at the Royal Aircraft Establishment, South Farnborough—The Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants (July 6). An engineer for the Fruit Storage Research Station, East Malling—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1 (July 6). A lecturer in pharmaceutics at the Chelsea School of Pharmacy—The Principal, Chelsea Polytechnic, Manresa Road, S.W.3 (July 6). A whole-time assistant (male) to the Public Analyst—The Secretary, Health Department, Grey Friars, Leicester (July 6). An assistant lecturer in mechanical engineering—The Principal, Municipal College of Technology, Manchester (July 8). An assistant lecturer in mechanical engineering at the Bath Municipal Technical College—The Director of Education, Sawclose, Bath (July 8). A resident engineer in connexion with the Sea Wall and Embankment Scheme—The Town Clerk, Municipal Offices, Liverpool (July 9). An assistant lecturer in electrical engineering at the Technical College, Bradford—The Director of Education, Town Hall, Bradford (July 10). A headmaster for the Sandown County Secondary School—The Director of Education, County Hall, Newport, I. of W. (July 11). A full-time assistant to take charge of the electrical engineering National Certificate courses—The Principal, Technical College, Wolverton, Bucks (July 12). A resident lecturer in mathematics with subsidiary science—The Principal, Saltley Training College, Birmingham (July 12). An assistant water engineer—The Town Clerk, Town Hall, Bexhill (July 12). An honours graduate as demonstrator in zoology—The Secretary, Queen's University, Belfast (July 13). A lecturer and demonstrator in pharmacy—The Principal, Central Technical College, Suffolk Street, Birmingham (July 13). An engineering assistant in the Highways and Bridges Department of the Surrey County Council—The Clerk to the Council, County Hall, Kingston-on-Thames (July 13). A professor of municipal engineering and town planning and a professor of railway and road engineering at the Royal School of Engineering, Giza, Cairo—The Director, Egyptian Education Office, 39 Victoria Street, S.W.1 (July 15). A full-time teacher for the Marine Engineering Department at the L.C.C. School of Engineering and Navigation, High Street, Poplar, E.14—Education Officer (T.1a), The County Hall, Westminster Bridge, S.E.1 (July 15). A part-time instructor in mechanical engineering—The Principal, Technical School, Watford. A principal of the Kenrick Technical College—The Director of Education, Education Offices, Highfields, West Bromwich. A test assistant to assist in chemical analysis of metals and alloys—The Chief Superintendent (quoting A.355), Royal Aircraft Establishment, South Farnborough, Hants. An assistant mechanical engineer for the Railway Department of the Government of Ceylon—The Crown Agents for the Colonies (quoting M/1581), 4 Millbank, S.W.1. A mechanical engineer in the Ministry of Public Works, Cairo—The Chief Inspecting Engineer, Egyptian Government, 41 Tothill Street, S.W.1. An assistant experimental officer for design duties for Government Establishment at Biggin Hill, Kent—The Secretary, R. E. Board, 14 Grosvenor Gardens, S.W.1.

Our Astronomical Column.

Origin of the Planetary System.—The May issue of *Mon. Not. R.A.S.* contains a paper on this subject by Dr. H. Jeffreys. He gives a résumé of various theories, starting with that of Buffon, who suggested that a massive comet struck the sun. Many subsequent theories supposed that the near approach of another star to the sun caused the outrush of a stream of matter from it by tidal action. The rotations of the sun and planets were explained as due to the return of a portion of the expelled matter to them after it had received a transverse deflection, from the attraction of the star in the case of the solar matter, or of the sun in the case of that returning to the planets. He examines this suggestion numerically, and finds that it does not give rotations of the right order for the large planets. He then examines the suggestion that the other star actually collided with the sun, and that as they separated a long filament of matter was drawn out between them; this, like the tidal filament in the theory of approach without collision, is supposed to have broken up into the planets. It would also receive a rotational motion by the pull of the other star. On certain assumptions, Jeffreys finds that the mass of the filament might be 1/500 of the sun's, and that the periods of rotation of the resulting planets would be of the order of 8 hours, in good agreement with the actual values for the large planets.

Objections had been made to the tidal theory on the ground that close approaches of stars would be extremely rare; obviously actual collisions would be rarer still, so the adoption of the theory would seem to imply that planetary systems are excessively rare in the universe.

Periodic Comets.—*L'Astronomie* for May contains an article by M. F. Baldet in which he gives a useful table of elements of all the comets known to have periods less than 170 years. It is quite up-to-date and includes the two most recent discoveries, Pons-Forbes and Schwassmann-Wachmann II. There are two lists, the first consisting of thirty-one comets observed at more than one apparition. Three of these are marked with an asterisk, indicating that the identity of the objects seen at the two returns is not absolutely certain; twenty-two of them belong to Jupiter's family, one to Saturn's, two to Uranus's, five to Neptune's, and one has a period of 164 years (seen in 1742 and 1907). The second list contains those seen at only one apparition; it contains thirty-five comets, twenty-two of which belong to Jupiter's family; of the others, five have periods between 11 years and 18 years, two between 40 years and 46 years, three between 64 years and 80 years, and three exceeding a century. Two comets of the second list are due at perihelion in the present year. Mr. F. R. Cripps has computed the perturbations by Jupiter of Giacobini's comet 1896V from its discovery to the present time; he finds perihelion occurs next September and gives a search ephemeris in the *B.A.A. Journal*, No. 7. The *B.A.A. Handbook* gives ephemerides for Perrine's and Metcalf's comets, both of which are due at perihelion this year.

Research Items.

oyle as a Philosopher of Science.—In the recent of *Archeion* (vol. 11, No. 1, pp. 1-12), G. W. ggs estimates Boyle in his capacity of a critical constructive philosopher. The author justly rves that Boyle has become a figure of uncertain ortance in science; his claim to recognition is lly based upon the law associated with his e, and upon rather vague statements to the effect he is the father of modern chemistry. The bulk is writings, and the dryness of his style, have otless combined to prevent his ideas from receiv- adequate attention by modern historians of ace. Mr. Spriggs shows that Boyle introduced h improvement in scientific reasoning, acutely cised the old and vexed question of the 'qualities' odies, and, by his conceptions of *minima* (small vided particles) and 'local motion', paved the for fundamental advances in scientific thought. n experimental investigator he was seldom sur- ed for patience, resource, and accuracy, while in y of his penetrating analyses of his observations o be found the germs of ideas current even to-day. did much to clear away the scholastic under- rth which hindered scientific progress, and formu- l conditions under which scientific work should arried out in order to discover the truths of ure. It is clear from Mr. Spriggs' all too brief that a full study of Boyle's writings would be ry welcome contribution to the history of science.

ock Carvings in the Italian Alps.—In *Antiquity* une, Mr. Miles C. Burkitt discusses the origin and ose of the rock carvings on the slopes around te Bego in the Italian Maritime Alps. The only ematic study of these carvings in the neighbourhood ordighera was that made by Mr. Clarence Bicknell, beginning in the year 1897, in the following ty years made rubbings of some 15,000 carvings. carvings fall into three classes: (1) Animals; eapons and tools; (3) signs, patterns, and scenes. animals are predominantly oxen. There are ral human figures, mostly associated with ghing scenes. The drawings are nearly all con- ionalised, and the figures represented as though from above. The weapon most commonly figured e triangular dagger with a handle. The halberd so shown. As the carvings are at the head of ys leading up to Monte Bego, and this mountain important cyclonic centre, of which the peasantry recognise the importance in connexion with the her, it is suggested that the carvings may be the ession of a seasonal agricultural cult which took orm of an annual pilgrimage such as those which been perpetuated in Italy under the Church. object of the pilgrimage would be to secure her propitious for the crops and animals from the of the mountain. As regards their age, there is vidence of habitation before the period of the ngs, and though culturally all the carvings can ssigned to the Early Bronze Age, it does not sarily follow that they can be associated in time the industry of the lake dwellers. On the other , the Iron Age peoples do not appear to have trated these mountains, but the absence of any tian symbol shows that they must have been uced prior to A.D. 300.

sociation of the Tuatara Lizard with Nesting ls.—A note on some features of this curious iation between a lizard and a bird appears in the al scientific number of the *Municipal Record* ne Auckland City Corporation, issued on the occasion of the visit of the New Zealand Institute Science Congress in January last. Tuataras still live in fair numbers on eight or ten groups of islands near East Cape, and these are inhabited also by different species of petrels. In many cases the burrows of the petrels are shared by tuatara and petrel during the nesting season, while in the winter, when old and young petrels have departed for the northern hemisphere, the tuatara digs itself in at the end of the burrow to hibernate. The association as a rule is one of *laissez faire*; both petrel and tuatara, the note relates, sleep during the day, and at night, when the lizard issues to hunt nocturnal insects, the petrel also goes about its business. Occasionally the lizard may devour the solitary chick of the petrel, but often it just leaves it alone. It appears that in the first instance the burrows are made by the petrel, but the lizards are long-lived, and, surviving the birds, eventually may remain sole occupants of the tunnel.

Effect of Low Temperature on Mitosis.—F. G. Spear (*Arch. f. exp. Zellforsch.*, 7; 1928) records observations on the effect of low temperature on mitosis in tissue obtained from the choroid and sclerotic of chick embryos of 7-8 days' incubation grown in fowl plasma and chick embryo extract on coverslips each inverted over a hollow-ground slide. The cultures were placed in a cold room at 0·5° C. for four hours and then incubated at 37° C. The duration of mitosis in chick tissues at 38° C. varies from 23 to 65 minutes (Levi, W. H. and M. R. Lewis, and Strangeways); at 28° C. the process takes about twice as long (Lambert and Hanes) and at lower temperatures is further delayed or arrested. Probably those cells which are in the later stages of mitosis when the culture leaves the warm incubator for the cold room pass through to completion, those in the early stages of mitosis proceed for a time and become arrested when the temperature of the culture falls to between 10° C. and 0° C. On re-incubation after chilling, the majority of these cells resume the process of mitosis. Chilling interferes with the initiation of mitosis, and there is no evidence of the resumption of this process until after 80 minutes' incubation. From this time there is a steady increase in mitosis until a maximum is reached about the 9th hour after chilling, when the number of cells in mitosis exceeds that in the controls by 60 per cent, after which there is a gradual fall up to the 13th hour of incubation. The fall in number of cells in mitosis seen during the first 5½-hour period of incubation subsequent to chilling is almost exactly compensated by the increase during the second 5½-hour period.

Vaccination of Silkworms.—Among the diseases to which silkworms are subject and which cause considerable mortality are those known as yellowness (giallume) and flaccidity. In Parts I.-V. of the *Rendiconti* of the Reale Istituto Lombardo di Scienze e Lettere for the current year, Dr. Domenico Carbone gives the results of experiments, made in conjunction with Signorina Elena Fortuna, on the vaccination of the silkworms with material prepared from the whole of the microflora of the diseased worms. Various preparations of vaccine made in different ways were employed and the mode of administration was either oral alone—by means of leaves immersed in the vaccine solution and then redried—or oral and cutaneous (spraying) together. The number of experiments made is as yet small, but the results, although not entirely consistent, indicate that distinct diminution in the mortality due to these two diseases

may be affected by the vaccination. The immunity appears to be specific.

Experimental Hop Drying.—The correct rate of drying hops is an important matter to the hop grower, since the colour and aroma by which the finished product is judged for brewing purposes are guaranteed only by prolonged and therefore expensive drying at a low temperature. More than twelve hours, for example, are required at temperatures below 120° F. The seventh season's work (1927) at the experimental oast of the Institute of Brewing, Paddock Wood, had as its principal object the determination of the most economical drying and storage conditions, and some interesting results are summarised by A. H. Burgess in the May issue of the Institute's *Journal* (**35**, 235; 1929). The actual (T) and minimum (M) times of drying in minutes were shown to be related to the loss of water (L) in oz. per square ft. of kiln floor, and the air speed (a) in ft. per min. by the equation $T = M + 87{\cdot}3\ L/a^{1{\cdot}047}$. M was found to depend principally on the temperature and to a less extent on a. Hops dried at above 104° F. showed a decrease in preservative properties, probably on account of a reduction in the proportion of so-called α-acid, though hops sterilised at 212° F. had higher preservative properties than the same hops dried in air at 140° F. Hops sterilised by treatment with sulphur dioxide, or dried in nitrogen at 212° F., however, showed a decrease in preservative value, and the effect of the former gas on the colour was no more marked than that produced by sulphur burnt in the ordinary way. The present type of intermittent kiln was shown by humidity measurements to produce very uneven drying, and a continuous type is considered more suitable. On the other hand, this lack of uniformity is partly compensated by diffusion of the moisture, particularly from the strigs to the bracts, during the cooling period.

The Coral Reefs of Oahu.—The island of Oahu in Hawaii is surrounded by a fringing reef and also shows fossil reefs in certain parts. Mr. J. B. Pollock publishes his researches on the nature and origin of these reefs in *Bulletin* 55 of the Bernice P. Bishop Museum, Hawaii. The fringing reef is in a state of active growth and is covered, like the fossil reefs up to 20 feet above sea-level, by coralline algæ and corals, the former predominating. Very few corals are found near the zone of breakers. The present fringing reef has developed since the last change in level of the sea, and began its growth at a depth of probably three fathoms or less. If the most abundant organism in the reef, a species of crustaceous alga, be taken as a basis for calculation, the rate of growth of the reef must be about 18 feet in 5000 years. Mr. Pollock insists that the study of these reefs gives no support to Darwin's subsidence theory. There is no barrier reef with lagoon. The fossil reefs were all formed during a time when the sea stood higher than it does at present, but there is no evidence by which to determine definitely their ages. The sea bottom around Oahu gives Mr. Pollock no evidence of a submarine shelf such as is demanded by the glacial control theory. Outside the reef the slope is gentle to a depth of 40 fathoms and then more rapid to 100 fathoms. He regards the slope of the sea floor as being very similar to that of the continental shelf.

Electron Waves.—The experiments of Drs. Davisson and Germer on the polarisation of electron waves, a preliminary account of which was published in NATURE last year (Nov. 24, p. 809) are described in detail in the May number of the *Physical Review*. The principle which they have employed is simple, being that of the Nörrenberg polariscope, with nickel crystals instead of mirrors, an 'electron gun' in place of the source of light, and a Faraday cylinde to receive the twice-reflected beam. The actua apparatus is most complicated, and consists of a elaborate metal structure which is built into a exhausted glass vessel, and so designed that there i freedom of motion between the appropriate componen parts, whilst, at the same time, currents of only som 10^{-11} ampere to the collecting cylinder can be measure with accuracy. The assembly of the apparatus is matter of some delicacy, and the planning and carry ing out of the experiments a notable achievemen The results obtained are in agreement with Pro C. G. Darwin's theoretical prediction that an initiall unpolarised beam of electrons should remain un polarised after diffraction by a grating, provided tha the forces responsible for the scattering are electri rather than magnetic in origin.

Secondary Cosmic Radiation.—It has been notice in work with the Wilson expansion apparatus tha even when very great care is taken to avoid radio active contamination, fast β-rays of uncontrolle origin occasionally appear, shooting across th chamber in almost straight lines. From the sma linear density of the ions in their trails, it is certai that these particles are of exceptionally high speed and the attractive hypothesis that they represen secondary electrons produced outside of the chambe and in its walls by the ultra-gamma cosmic radiatio has now been examined by D. Skobeltzyn (*Zeitschri für Physik*, May 11, p. 686), using the method men tioned in his recent letter to NATURE (Mar. 16, p. 411 Thirty-two trails of this type appeared on makin some six hundred exposures, and in only one instanc was the trajectory of the particle markedly affecte by the magnetic field in the chamber. The energy o the majority of the particles was not less tha 15 million electron-volts. Taken in conjunction wit the frequency with which they occur, and the fac that they have a predominantly vertical direction o motion, this leaves little room for doubt that the are secondary products of the cosmic radiation. Th exact mechanism by means of which they are produce is nevertheless not certain. They exhibit a marke tendency to occur in groups of two or three, whic are not contemplated in the usual Compton-Deby theory of the scattering of radiation, and there is als some indication that fast protons may be present, a well as the β-particles. If this can be substantiated it will be difficult to avoid the conclusion that th cosmic rays are able, directly or indirectly, to effe the disintegration of the *nucleus* of an atom.

Specific Heats at Low Temperatures.—An accoun of the determination of the specific heats of aceton methyl-, ethyl- and *n*-propyl alcohols at low tem peratures is given by S. Mitsukuri and K. Har in the *Bulletin of the Chemical Society of Japan* fo March. Temperatures down to about −110° C wer employed, and in order to overcome the difficulty o maintaining the environment of the calorimeter a constant temperature, a method was used whereb the temperature of the calorimeter surroundings wa allowed to increase at a regular rate.

Heats of Combustion of Organic Compounds.— critical survey of previous work on the heats of com bustion of organic compounds has been made b M. S. Kharasch and is published by the U.S. Burea of Standards in the *Journal of Research*, vol. 2, No. A table of 'best' values, including all the availab data, is given, together with a complete bibliography. method is described for calculating the heat of combu tion from the structural formula of the substance, an in most cases the calculated and observed values agre

thin 1 to 2 per cent, that is, within the limits of of the experimental determinations.

nganese in Foodstuffs.—The results of an in-gation of the manganese in foodstuffs and a od for its analysis are described by Newcomb Sankaran in the *Indian Journal of Medical rch*, vol. 16, No. 3. The ash of the foodstuff dissolved in nitric acid and the manganese then sed to permanganate by ammonium persulphate ie presence of silver nitrate as catalyst. The nt of permanganate was estimated by the depth loration. Manganese appears to be present in odstuffs, with the exception of oils and cane-, and a sample of oatmeal contained as much as nilligrams per kilogram. In cereals most of the anese appears to be in the outer layers of the s, and hence much of it is often removed when are prepared for use as food.

e Radiation Hypothesis of Chemical Reaction.—ermal unimolecular reactions are really photo-ical reactions in which the frequency of the ating radiation lies within the infra-red region, the thermal reaction rate should be increased xposing the system to such radiation. W. Ure R. C. Tolman have applied this test in the of the racemisation of *d*-pinene, which is known e unimolecular, by subjecting the pinene to tion of wave-lengths up to 3 μ at such a tem-ure that the thermal reaction was just appre-e. Their experiments, which are described in the *nal of the American Chemical Society* for April, that large increases in the density of radiation ese wave-lengths has no effect on the rate of nisation. The work of Lewis and Mayer, also ed out with pinene, is critically discussed, and conclusion that radiation up to wave-lengths of is inactive, is not accepted by Ure and Tolman.

acking Petroleum.—In two recent papers in the *edings of the Royal Society* (vol. 116, p. 501, ol. 120, p. 247), Prof. H. A. Wilson has developed heory of the chemical equilibrium of mixtures of ffins and unsaturated hydrocarbons, and has n that the composition of both the liquid and apour phases can be calculated approximately if emperature and pressure of the system are known. third paper, in the May issue of the *Proceedings* 6), he has now applied these results to the rtant practical problem of the 'cracking' of leum, in which the composition of an oil is ed by heating it under pressure, the product being wards fractionated. He finds good agreement een the actual course of the reactions and that cted from thermodynamical reasoning, both when ressure is sufficiently high to keep the greater of the oil in a liquid state, and when the cracking formed on the vapour, in spite of the fact that ugh it is possible to make some allowance for the ition of coke, the theory has not yet been ded to allow for the presence of naphthenes and atic hydrocarbons. Apart from its possible cations in petroleum technology, Prof. Wilson's is of great interest in that it seems to confirm iew that was expressed by Berthelot so long ago 66, that a mixture of hydrocarbons will proceed uilibrium if only it is raised to the appropriate temperature.

ctric Power in Quarries.—In the *Mining Electri-ngineer* for May there is an interesting descrip-f the Blackford quarry of the Midlothian County il. The improved methods of quarrying, and apidity with which necessary repairs for the can now be carried out, have proved a great boon to the county. The quarry is worked by an electric supply taken from the works of the Edinburgh Corporation, and transmitted at high voltage to the quarry, where it is converted to a pressure of 400 volts. The first operation in quarrying road material is to break up the rock. This is done by the ordinary methods of drilling and blasting. The broken material is separated by hand into portions larger and smaller than about five inches. The wagons containing the material are transported by an endless rope haulage to the feeding platform, where the large material is tipped into a primary crusher, and the smaller into a shaker feed. The crusher is a massive piece of machinery with manganese steel jaws capable of reducing the material to portions not greater than five inches. The output is then transported to the secondary crushing plant. A magnetic pulley is used to prevent any 'tramp' iron from passing into the crushers and possibly damaging them. The crushers are capable of producing about 50 tons per hour, the stones all being less than $2\frac{1}{2}$ inches. By suitable screens the material is graded, some of it passing to a granulator where it is further reduced. The storage bunkers have a capacity of 800 tons each, and are divided into compartments depending on the size of the graded material. Each compartment has a sliding trap-door over the loading dock so that the material can be transferred directly to the wagons.

New Steam Tables.—An interesting report entitled "Extended Steam Tables" is made by Prof. H. L. Callendar to the Institution of Mechanical Engineers. The report is from the British Electrical and Allied Industries Research Association, with the assistance of which it recently became possible to measure the total heat of both water and steam at pressures up to 4000 lb. per square inch and temperatures up to 750° F. The need for accurate knowledge of the properties of steam at high pressures and temperatures, including the critical region, has been acutely felt recently, and this is a very welcome contribution to the subject. The new data obtained are quite inconsistent with the van der Waals theory, but fall into line with the basis of the Joule-Thompson equation. A general account is given of the theory and development of an equation of the latter type with suitable constants to give a good fit over the whole range, together with a skeleton set of tables calculated from the new equation. The equation and tables are not intended to be final, but are given as a basis for discussion and comparison. The apparatus and methods of taking and reducing the observations are dealt with briefly, since they have been fully described in previous articles dealing with investigations in lower pressure regions, to all of which articles references are made. The method of analysing the observations is illustrated by a few actual examples, the analyses chosen for this purpose being those of the observations taken with the object of investigating the effect of air and other impurities on the equilibrium between steam and water. Beyond the critical point, the effect of small impurities is very pronounced and most difficult to determine, and while this obstacle has been surmounted in this instance, the possibility readily suggests itself of great difficulty in the practical use of steam at such pressures due to instability resulting from small impurities. At low pressures the values given in the tables do not differ greatly from the previously published Callendar tables, but the differences increase with the pressure and are of considerable magnitude at the highest pressures, where the new tables tend to agree more closely with the recently published Mollier tables.

The National Physical Laboratory, Teddington.

INSPECTION BY THE GENERAL BOARD.

ON Tuesday, June 18, the General Board of the National Physical Laboratory made its annual visitation. A large number of visitors, including members of scientific and technical institutions, Government departments and industrial organisations, were present, and were received by Sir Ernest Rutherford, president of the Royal Society and chairman of the General Board, Sir Richard Glazebrook, chairman of the Executive Committee, and the Director, Sir Joseph Petavel.

Numerous experiments were in progress.

In the Aerodynamics Department the investigation on wing flutter has been extended to include the case of tail flutter, and the research has reached a stage at which recommendations can be made for the prevention or minimisation of flutter in given cases, except at flying speeds well outside the normal range. Demonstrations of the nature of wing and tail flutter were given, together with illustrations of some methods of its prevention.

The drag on an aerofoil is closely correlated with the nature of the flow close to its surface, and an experiment was in progress to determine the points at which the flow changes from a laminar to a turbulent character around a body of good aerodynamic shape. At appropriate points on the body were fitted hot wire anemometers constructed of platinum wire a few hundredths of an inch thick. In series with the anemometer wire was the primary of a transformer, and together they formed one arm of a bridge. A definite steady temperature was attained in the platinum wire with the bridge in balance. Turbulence in the boundary layer produced rapid fluctuations in the temperature, and therefore in the current through the anemometer wire, with corresponding changes in the secondary current, which was amplified by an appropriate amplifying system.

In another experiment the velocity distribution across the boundary layer was being studied at a number of points along the median section of a Joukowski aerofoil. In order to minimise external interference a very small Pitot tube is used, and can be advanced in steps of one-thousandth of an inch from outside the wind tunnel. The mechanism for advancing the Pitot head is entirely enclosed in the aerofoil, and consists of an electromagnetically operated pawl actuating a ratchet wheel attached to a finely threaded spindle passing through the Pitot tube support.

A demonstration was also given of an extreme case of body-wing interference in an aeroplane model in which the drag of the body in the presence of the wing became negative, their combined drag thus being less than the sum of their individual drags.

In the Engineering Department a machine for making tests in tension, compression, or bending up to a maximum load of twenty-five tons was shown. The machine is fitted with a six-speed gear-box, the intervals being covered by varying the speed of the driving motor. By this means rates of travel from one-thousandth of an inch to two and one-half inches per minute can be imparted to the cross-head. Autographic records of stress and strain can be taken on a recording drum.

Of interest also was apparatus for the determination of the slip and coefficient of friction of belts under running conditions. The belt passes round two large cast-iron pulleys and the sum of the tensions in the tight and slack portions can be adjusted by means of lever mechanism attached to one of the pulleys. The difference in the two tensions is obtained by means of a torquemeter on the driving shaft. The pulley speeds are measured by a speed counter connected differentially to them. From the data so obtained the belt slip and the efficiency of the power transmission can be determined.

The investigation on the mechanism of deformation in single crystals, described last year, has been extended to include the hexagonal type such as zinc and the rhomboidal type such as antimony, and it has been confirmed that deformation occurs by slip on the basal plane. Apparatus has been devised whereby Laue photographs can be taken of a single crystal of tungsten at tensile stresses up to one hundred and four tons per square inch.

For experiments on road skidding a special motor cycle side-car has been constructed equipped with mechanism for recording the load, braking force, and force normal to the wheel, which can be set at any desired angle with the direction of motion. Records have been obtained under various climatic conditions up to speeds of about thirty miles per hour.

For the study of the deformation and fracture of metals and alloys under prolonged load at high temperatures, special apparatus has been devised in the Metallurgy Department. To enable the behaviour of the specimen to be followed during load, the surfaces must be polished and kept free from contamination. For this purpose the test-piece is enclosed in a long silica tube dipping into mercury at the bottom and communicating at the top with exhausting pumps. The mercury column which rises in the tube serves as a seal. A suitable furnace encloses the tube and specimen, temperatures of the order of 1000° C being attained. The load is applied to the lower end of the specimen by a lever and weight. In the case of specimens which are volatile *in vacuo*, a neutral atmosphere can be introduced.

Apparatus for the determination of the heat which becomes latent in wire-drawing was shown. The wire is kept in tension by suitable springs attached to pulleys which the wire traverses. The calorimeter in which the die is placed is a Dewar flask. The work done is determined from the tensions in the springs, the difference between this and the heat generated being the latent heat of plastic deformation. An electrical method is used to measure the mean extensions of the springs, platinum-iridium contacts attached to them being free to slide along platinum wires included in two bridge circuits. The arrangement of the galvanometer and potentiometer is such that the difference between the two extensions is determined directly. The calorimeter is calibrated electrically.

Specimens of alloys for high temperature tests and of special refractories, both developed in the department, were on view. Of the former, one nickel chromium-iron alloy containing proportions of carbon, silicon, and tungsten was found to have an ultimate breaking stress of thirty tons per square inch at 800° C., and at this temperature to withstand without breaking a steady load of five tons per square inch for 68 days.

In connexion with the determination of the metre in terms of wave-lengths of light, a new wave-length comparator is under construction in the Metrology Department. To minimise temperature effects the comparator is thermally insulated in a double walled enclosure and the room temperature is controlled thermostatically. In order to determine its tem-

ture accurately the invar end gauge about 1 metre , which forms the Fabry-Perot étalon, is wound n its own resistance thermometer. The air in the is heated electrically and circulated.

n interference method has also been developed neasuring the lengths of block gauges without lving the wringing of glass plates to their end sur-s. The gauge to be measured is mounted vertically ptical contact with the upper surface of a flat, zontal steel plate. The difference in height of two reflecting planes formed by the upper end of gauge and the surface of the steel plate is deter-ed in terms of light wave-lengths with reference lightly silvered glass plate supported above the ge and parallel to the steel plate.

or comparing the pitches of six-inch lengths of ing screws a screw-pitch calliper has been devised he department. The instrument rests upon the w on two inverted V's and is fitted at each end n a ball-ended projection engaging a thread. One hese is rigidly attached to the calliper, the second g attached to one end of a lever operating a dial cator.

n the Physics Department a distant-reading stance thermometer outfit embodying novel ures has been developed for work in connexion n the cold storage of food. The bridge is direct ling and embodies three dials giving readings in s of 10° F., 1° F., and 0·1° F. The switch gear is rranged that the battery current is completed so long as one of the dial knobs is depressed. each dial there is an appropriate resistance in the ery circuit sufficient to prevent violent deflection ne galvanometer needle if the bridge should be out alance when the knob is depressed.

pparatus for the determination of the latent heats iquids at various temperatures and the specific ie of refrigerants was also shown in the Heat ision. In the former the calorimeter is supported novel form of constant temperature enclosure sisting of a spiral of iron tubing cast into the walls n aluminium container. The spiral is connected refrigerating plant circulating ammonia gas, and desired temperature may be produced and main-ed constant. The heat required for evaporation alanced by a measured electrical supply. Liquids lied include sulphur dioxide, methyl chloride, and tane.

n the latter apparatus two reservoirs connected tube and stop-valve are immersed in a constant perature bath. One reservoir contains the liquid gerant to be studied and the other is connected n evacuating system. By repeated evacuations ne latter and refilling with vapour from the liquid ainer, the weight of vapour required to fill the iver can be determined, so giving the specific ume directly.

n the Sound Division apparatus for the measure-t of sound absorption of materials by reverbera-methods was demonstrated. The reverberation od of an empty room with hard walls is first deter-ed, after which a definite area of the material to ested is introduced and the period again deter-ed. From the observed reduction in the period absorption coefficient may be calculated. A valve lator and loud speaker arranged to oscillate over efinite frequency range are used to produce the nd, and a microphone, receiving set, and reflecting anometer serve to record the decrease in sound nsity on photographic paper, the time scale being n by an electrically operated tuning-fork and nic motor.

pparatus for the measurement of X-ray intensity erms of the international unit was also shown. Normally the intensity has been measured by the colour change of barium platinocyanide pastilles when exposed to a given quantity of X-ray radiation. The accuracy of this method is limited by the sensitivity of individual observers to small colour changes and by the dependence of the reaction on the wave-length. The new apparatus consists of a rectangular ionisation chamber fitted with two parallel graphite electrodes through which the X-ray beam passes, graphite being chosen as its atomic number approximates closely to that of air. The normal guard ring is used and the potential difference across the plates is sufficient to produce saturation. A string galvanometer measures the ionisation current.

In the Optics Division a bench and measuring apparatus have been constructed for the calibration of electric lamps as master-standards of total radiation. A Moll open thermopile and potentiometer system specially designed to eliminate or minimise the effects of parasitic electromotive forces are used to determine the radiation. It is possible to compare the standards directly with a suitable black-body furnace.

In the Electric Standards Division a valve generator source of low and telephonic frequencies was shown in operation. Two oscillators are used, one possessing a fixed frequency of about one hundred thousand cycles per second, while the frequency of the other is continuously variable from about ninety to one hundred thousand cycles per second. Small voltages from each oscillator are applied to the grid of a detector valve and the resulting beat tone is amplified in three stages. The output from the final stage of amplification is very constant over a frequency range of from thirty to ten thousand cycles per second, the voltage being about one hundred.

In the High Voltage Building was to be seen apparatus which has been developed for research work on behalf of the British Electrical and Allied Industries Research Association in connexion with the dielectric losses at high voltages in power transmission cables. This apparatus consists of a large parallel plate condenser and a water-tube shielded resistor, each having zero phase angle. With these the losses in cables have been measured at voltages up to two hundred thousand. Use is made of half-wave rectification of the capacity current flowing across a spark-gap in the high voltage circuit to measure the peak voltage, which is calculated from the mean value of this current, the frequency and the known capacity of the gap.

A demonstration was given of the action of a three-phase field on a dielectric. The latter, in the form of a paper cylinder free to rotate about a vertical axis, was set at the centre of a three-phase field. The ensuing rotation of the cylinder demonstrated the presence of tangential stresses on the dielectric.

In the Wireless Division sensitive apparatus has been constructed for the rapid and accurate measurement of the capacities and power factors of condensers. A substitution method is adopted employing a condenser and series resistance in a tuned circuit, the condenser under test being substituted for a standard variable condenser. High frequency oscillations are used and the results are given in terms of the capacity of the standard condenser and the values of the resistance.

Transmitting and receiving circuits have been developed for work on wave-lengths of less than twenty-five metres. A transmitter operating at two hundred watts on a wave-length between four and ten metres, and a portable loop receiver working over the same range, were shown. Of interest also was a laboratory two-valve oscillator working on a wave-length of 1·8 metres. The inductance in this consists of a small rectangular coil the sides of which are about

an inch in length, while the capacity is provided by the inter-electrode capacities of the valves.

A single loop direction finder operating on a wave-length of seven metres is capable of receiving signals at distances up to eight miles.

In the Photometry Division improvements have been made in the apparatus for investigating the effect of glare on the brightness-difference threshold, the chief new feature being automatic control of the rate of change of brightness of the test spot. The movement of the lamp producing this spot is controlled by an electric motor, the speed of which is proportional to the distance of the lamp from the focal plane of the projection lens. This ensures constant percentage increase in unit time of the brightness-difference between the test spot and the surrounding field.

Of interest also was an investigation directed towards the prevention of fading of water-colour pigments. A sufficient range of pigments to cover approximately the visible spectrum is exposed on different fabrics to sunlight and to the radiation from a carbon arc. Protection is given by plain glass and by various types of ultra-violet absorbing glass. From the results obtained it is hoped to ascertain the best conditions for minimising the fading of water colours.

In the William Froude Tank a novel method of determining the wind resistance and centre of effort of ship superstructures by measurements in water was demonstrated. The superstructure complete with funnels, masts, derricks, etc., is towed upside down in water at slow speeds. Then, since for the same value of Reynolds's number the fraction (resistance)/(length)^2 (speed)^2 (density) is the same for air and water, the resistance in air can be determined from the measured value of the resistance in water.

Jealott's Hill Research Station.

THE future of agriculture is bound up with the development of the fertiliser industry. Farming without manures, the exploitation of the natural resources of the soil, is characterised by large areas and declining yields; it is only rendered possible by cheap and abundant labour on one hand or a high degree of mechanisation on the other. The first step towards more permanent conditions and a higher level of production is usually the fixation of atmospheric nitrogen by the agency of leguminous crops, aided when necessary by the addition of phosphate and of lime. The use of animal manures follows. Then in the search for nitrogen, farmyard manure is enriched by the feeding of purchased feeding stuffs. At this stage the need for further phosphate became insistent, and we reach the level of the best British farming of the 'seventies.

In recent years in the older countries this system has been pushed one stage further by the scarcity of land, the introduction of crops which make a great demand on the soil, and the necessity of securing a high production per acre. On the lighter soils, particularly, the need for more potash makes itself felt, and for certain crops in the rotation further nitrogen is still necessary. For a time, by-product sulphate of ammonia and Chile nitrate of soda could provide the necessary nitrogen. In the War period and the years which followed, various processes of fixing atmospheric nitrogen were greatly developed, thus laying the foundation of an abundant supply of cheap nitrogenous fertilisers in all industrialised countries.

In the meantime, numerous field experiments in Great Britain and abroad showed that an increased amount of nitrogenous fertilisers could be consumed by farmers with advantage, particularly if supported by appropriate additions of phosphoric acid and potash. It was further shown that grass-land in intensively farmed countries, which hitherto had received phosphates, if it was manured at all, could also benefit from nitrogenous fertilisers under certain systems of management. The supplying of a range of nitrogenous manures suited to the varied conditions of Great Britain and the Empire, and the working out of their economical and effective use in practice, is the task which Imperial Chemical Industries, Ltd., has taken up. As the source of supply there is the huge synthetic nitrogen plant at Billingham-on-Tees, turning out as its main products sulphate of ammonia and nitro-chalk, the former being our leading source of nitrogen as regards tonnage and range of application, with almost a century of experience and experiments behind it; the latter a new product consisting of ammonium nitrate and chalk, which combines the advantages of nitric and ammonia nitrogen. There is, however, the staff and equipment at Billingham to manufacture further products as the need for them may arise; and one may expect to see in due course the production of ammonium phosphate, and by inclusion of the natural potash salts, a range of high grade mixed fertilisers similar to those which are becoming a feature of the continental market.

To develop the old and to investigate the new an expert agricultural service is a necessary complement to the producing organisation. Imperial Chemical Industries' Research Station at Jealott's Hill, near Maidenhead, which was opened on June 28, is designed to meet this need. It consists of a farm of some 440 acres, and a well-equipped laboratory containing the usual departments for the study of the many-sided problems of plant and animal nutrition.

The arable portion of the farm is devoted to experiments of modern design to test the effects of fertilisers on farm crops, with special reference to the use of I.C.I. products. In addition to the fertilisers mentioned above, ammonium chloride, urea, nitrate of lime, ammonium phosphate, and the German compound fertiliser 'nitrophoska', are being used. Experiments are also in view on the manuring of horticultural crops, a line of inquiry which has been somewhat neglected in the past but will assume greater importance in future. The grass-land is largely used for investigations and demonstrations of intensive systems of pasture management in which the use of generous applications of nitrogenous fertilisers is an essential feature.

This conversion of cheap inorganic nitrogen into the protein of young grass, and its further conversion into a saleable form by the agency of live stock, raises a series of practical and scientific problems which are being attacked energetically on the farm and in the laboratories at Jealott's Hill. The effect of the manurial treatment on the pasture itself from its botanical and chemical aspects is being worked out, the measurement of the digestibility of the resulting grass to various classes of stock is under investigation, while the question of how best to utilise the surplus which may arise in favourable seasons is being examined. At certain times of year, hay-making is uncertain and troublesome. Two alternative methods are being tested: the making of grass silage and the artificial drying of short young grass, which opens up the possibility of the production of home-grown concentrates or grass cakes. The latter process the outcome of the work of the Cambridge School

eing followed out in detail, using experimental
ng plants of various designs.
n the practical side, there are the agricultural
blems which arise when any considerable change
anagement is made. These are being studied on
farm, and as they are successfully met they are
onstrated to visiting parties of farmers. Thus,
e are demonstrations of the utilisation of in-
ively treated grass by young cattle (baby beef)
by dairy cows. In each case a food relatively
in protein is required. The economic side of
e trials and demonstrations is kept uppermost,
there is a special staff to work out and present
essential information.
Vith Jealott's Hill as a centre for direction, advice,
the examination of results, there extends a range
xperimental centres and demonstration areas in
at Britain, the Empire, and in foreign countries
re fertiliser tests are being made on practically
whole range of economic crops. In most cases
work is done in close co-operation with the
ting official agricultural institution both at home
abroad, and it is the policy of I.C.I. to make these
acts as real as possible.
early seven hundred guests representing every
nch of agriculture and its related industries were
sent on June 28 for the official opening of the
earch Station by the Right Hon. J. H. Thomas,
d Privy Seal. The weather conditions were ideal,
the arrangements for the comfort of the visitors
e admirably carried out. The importance of
cultural research in Great Britain and in the
pire, and the part which the new research station
play in this sphere, were set out by the chairman,
Right Hon. Lord Melchett, and by other directors
mperial Chemical Industries, Ltd.
he Jealott's Hill Station will take up its work
the good wishes of the other institutions already
blished in the field of agricultural research.

H. V. GARNER.

University and Educational Intelligence.

BIRMINGHAM.—At a degree congregation held on
e 29 the following degrees were conferred: D.Sc.
emistry) on Mr. E. L. Hirst; M.D. on Mr. W. D.
k and Mr. C. G. Payton. For the degree of
D. in science there were six successful candidates.

LIVERPOOL.—A further step towards the comple-
n of the School of Veterinary Science of the
iversity was taken on June 28, when the new
erinary Hospital was formally opened by Lord
ward de Walden in the presence of a representative
hering of those who have striven during the past
nty years for fuller facilities for veterinary research
the care of animals. This is the first occasion
which such an hospital is to be conducted by a
versity in Great Britain. The building is of
drangle form, and surrounds a central court with
ss roof. There is an operating theatre for large
mals, and ample accommodation has been provided
he form of animal boxes and stalls. In addition
re is a lecture theatre, and a museum, laboratory,
rating theatre, and a surgical ward have been
vided, the latter being specially designed for the
ds of small animals. There is also accommoda-
n for a resident surgeon and his staff. The institu-
n is intended primarily for research and instruction,
in all probability provision will be made for the
atment of domestic pets belonging to the poor.
R. Isherwood, lecturer in veterinary medicine
l honorary lecturer in clinical veterinary medicine and surgery, has been appointed administrator of the hospital, and will be associated with Profs. Share Jones and Gaiger in its direction.

ST. ANDREWS.—On Friday, June 28, Her Royal Highness the Duchess of York opened the new Graduation Hall, the gift of Mr. James Younger, of Mount Melville, Chancellor's Assessor in the University Court, and Mrs. Younger. The building is in North Street to the east of the College Chapel, and is capable of seating an audience of more than 1200 persons. The original designs prepared by Mr. Paul Waterhouse, who died in 1924, were carried out by his son, Mr. Michael Waterhouse. The actual cost, amounting to about £95,000, has been met entirely by Mr. and Mrs. Younger. Her Royal Highness, after declaring the Hall open and handing the deed of gift to the Vice-Chancellor, Sir James Irvine, was presented for the honorary degree of doctor of laws. Among the honorary graduates who were afterwards capped were Lord Blanesburgh of Alloa, and Profs. John Dewey of Columbia University, T. Percy Nunn of the London Day Training College, and A. E. Taylor of Edinburgh.

THE Joint Committee of the Royal Society and the University of Sheffield has appointed Dr. W. H. George to the Sorby Research Fellowship, tenable at the University of Sheffield. Dr. George will continue his work, begun at the Davy-Faraday Research Laboratory, at the Royal Institution, on X-rays and crystal structure.

APPLICATIONS are invited for the Drapers Company's research scholarship in dyeing, value £100 a year with remission of fees; the Joseph Blamires research scholarship for research in colour chemistry, value £100 a year with remission of fees; and the British Dyes research scholarship for research in colour chemistry, value £75 a year with remission of fees. Particulars and forms of application may be obtained on application to the Director of Education, Technical College, Huddersfield.

THE Air Ministry announces that six hundred aircraft apprentices, between the ages of fifteen and seventeen years, are required by the Royal Air Force for entry into the Schools of Technical Training at Halton, Bucks, and at Cranwell, near Sleaford, Lincs. They will be enlisted as the result of an open competition and of a limited competition which will be held by the Civil Service Commissioners and the Air Ministry respectively. Full information regarding the dates of the respective examinations, the methods of entry and the aircraft apprentice scheme generally can be obtained from the Royal Air Force, Gwydyr House, Whitehall, S.W.1. The scheme offers an opportunity to well-educated boys of obtaining a three years' apprentice course of a high standard.

A KING Senior Medal, consisting of a gold medal, has been founded by Mr. Sontsu G. King in memory of his parents, Mr. and Mrs. Sung-yuan Daw King, with the object of encouraging original investigations in natural history. The medal is to be awarded annually for the most meritorious work, selected by a prize committee appointed by the executive council of the Peking Society of Natural History, on the flora or fauna of China. Mr. King has also founded a King Junior Prize, consisting of a bronze medal and the sum of 20 dollars local currency, in memory of his brother, Mr. Kung-pao King, a charter member of the Peking Society of Natural History, to be awarded for the best collection of Chinese natural history objects with descriptive notes made by anyone under twenty years of age.

Calendar of Patent Records.

July 6, 1846.—One of the most common proposals for achieving perpetual motion has been to mount weights on a wheel in such a manner that they are free to move towards the periphery on the descending side of the wheel and towards the centre on the ascending side, the greater leverage thus given to those on the descending side serving, it is assumed, to produce the rotation of the wheel. James Thompson's invention, for which a patent was granted on July 6, 1846, utilises this principle to increase the power of a steam-engine, two oppositely disposed levers being fixed to the fly-wheel shaft, which are acted on by weights moved to and fro along the levers by crank motions.

July 7, 1856.—'Condy's fluid', a mixture of sodium manganates and permanganates, was the invention of Henry Bodman Condy and was patented by him on July 7, 1856.

July 7, 1884.—The first International Convention for the protection of industrial property was signed at Paris in 1883, and came into force on July 7, 1884. Its main provision allowed an inventor who had applied for a patent in any one of the signatory States to obtain a patent for the same invention in priority to other applicants in any other country of the union, protection to start from the date of the first foreign application. The International Union now comprises 42 States, including the self-governing dominions of the British Empire; Russia is the most notable exception.

July 8, 1876.—Blasting-gelatine—a mixture of nitroglycerine with 7-8 per cent of collodion gun-cotton—was invented by Alfred Nobel in 1875 and was patented by him in Sweden on July 8, 1876. The English rights were transferred under an old agreement to the Nobel Explosives Co., of Ardeer, but production of the new explosive did not start here until 1879, and large quantities were imported into Great Britain from the continent, where the manufacture had been very rapidly developed.

July 10, 1817.—The kaleidoscope was patented by David Brewster on July 10, 1817: "A new optical instrument called the kaleidoscope, for exhibiting and treating beautiful forms and patterns, of great use to all the ornamental arts—realising the idea of an ocular harpsichord".

July 12, 1799.—An invention for utilising the force of the waves of the sea was patented in France on July 12, 1799, by the Girards, father and son, of Paris. A float in the water is suspended from one end of a lever, the other end of which operates pumps, wheels, or mills. Or a boat is provided with gearing which is operated as the boat rises and falls by a rope, one end of which is anchored to the bottom of the sea and the other end weighted.

July 12, 1848.—An early electric incandescent lamp was patented by W. E. Staite on July 12, 1848, the filament being of platinum and iridium and operating in the air. Staite was also the inventor in 1846 of an arc lamp having two vertical carbons, the upper one of which was stationary and the lower one actuated by clockwork under the control of an electromagnet in the lamp circuit, so that the carbon was moved up and down as required.

July 13, 1781.—The compound steam-engine was first introduced by Jonathan Hornblower, whose patent for the invention was dated July 13, 1781. An engine was erected at the Tin Croft mine in Cornwall in 1792, but was found to give no greater efficiency than the Watt engine, and the experiment was abandoned. It was many years, in spite of its reintroduction by Wolff in 1804, before the principle of compounding was fully developed.

Societies and Academies.

LONDON.

Royal Society, June 27.—**Lord Rayleigh**: A photo electric method of measuring the light of the night sk with studies of the course of variation through th night.—**J. C. McLennan, M. W. Perrin, and H. J. Ireton**: The action of high-speed cathode rays o acetylene.—**Lord Rayleigh**: Fluorescent and pho phorescent excitation of mercury vapour by th resonance frequency and lower frequencies.—**T. Stern, B. S. Gosling, and R. H. Fowler**: Furth studies in the emission of electrons from cold metal An extension of Nordheim and Fowler's work o electronic emission from clean cold metals. It ex plains a wide range of experimental results obtaine with films of sodium (or tungsten). The normal stabl sodium film formed is mono-molecular and reduces th work function from 4·5 volts to somewhat less tha 2 volts. The currents concerned are of high density the space charge correction is negligible for the con ditions of the experiments discussed.—**A. E. H. Love** The stress produced in a semi-infinite solid by pressur on part of the boundary. The method of potentials invented by Boussinesq, is developed and applied t the case of uniform pressure over a circular area among others. The solution is also discussed arith metically with the object of throwing light on th technical question of the safety of foundations. Be neath a round pillar, there is a basin-shaped surfac possessing a roughly similar property. The form o this surface is determined. In these cases failur arises through excessive stress-difference. Tensil stress is greatest near the base of a pillar, or a corne of the base of a wall, and just outside it. It would no endanger a round pillar, but may be a cause of decide weakness if the boundary of the base of a wall or pilla presents a sharp corner.—**A. N. Shaw and H. E. Reille and R. J. Clark**: The ageing of standard cells: in creased accuracy in their use: and internationa comparisons.—**H. Quinney**: A comparison betwee the behaviour at the Ac_3 point of single crystal iro and polycrystal iron, both in the strained and un strained states.—**J. N. Pring and G. M. Westrip**: A electrometric method for the determination of ozon at high dilutions.—**C. F. Jenkin and G. D. Lehmann** High-frequency fatigue.—**J. S. Townsend and S. P MacCallum**: Ionisation by collision in monatomi gases. A discussion of some recent theories of con ductivity.—**R. C. Johnson and R. K. Asundi**: The structure of the high-pressure carbon bands and the Swan system. Both systems are due to a C_2 molecule Four new high-pressure bands have been found in the near ultra-violet, and two more in the near infra-red These, with the known bands, form a single vibrationa progression ($n' = 0$), and both systems represent transi tions to a common final state. The initial state of the high-pressure system is believed to be a *normal* $^3\Pi$ level and different in this respect from the two lower $^3\Pi$ levels, which are believed to be *inverted*.—**D. M. Newitt** Gaseous combustion at high pressures (13). The experimental data from explosions of various $2CO + O_2 + 4CO$, $2H_2 + O_2 + xN_2$ and $2H_2 + O_2 + xA$ mixtures a high initial pressures have been analysed, and mean molecular heats of nitrogen and steam have been calcu lated for the temperature range 289°—2600° to 3000° K and for carbon dioxide for the range 289° —3173° K. The results for nitrogen are in agreement with the generally accepted values, but those for steam and carbon dioxide are higher.—**R. J. Clark** On the direct determination of the electrostatic moments of molecules. Direct deflection in a rapidly varying field is used. Sodium and potassium atoms

either no permanent electric moment, or one is too small to measure. So far no polarisation ne field on these molecules has been found.—**A. R.** : On the criterion for stability of a layer of us fluid heated from below. Rayleigh gave a nematical account of the modes of instability of scous fluid heated from below with the special mption of zero tangential forces at the boundaries, found unexpectedly that the top-heavy layer of was stable until a certain temperature gradient, tive upwards, was exceeded. Jeffreys has reduced problem to the solution of a linear differential tion of the sixth order with constant coefficients, complete solution of which is now given.—**R. B.** e : The absorption coefficient for slow electrons ercury vapour.—**F. L. Usher** : A mechanism of inisation.—**H. R. Hassé** and **W. R. Cook** : The rmination of molecular forces from the viscosity gas.—**J. C. McLennan, A. B. McLay,** and **M. F. rford** : The spark spectrum of thallium (Tl III).—**A. Fisher** : Tests of significance in harmonic ysis.—**F. H. Constable** : Sulphide colours on llic copper. Spectrophotometric methods show the sequence of colours produced when a mixture ydrogen sulphide and air or oxygen acts on llic copper is a series of true interference colours. characteristic silvery colour is due to the flatness ne reflection maximum in the intensity wave-h curve.—**G. I. Taylor** : Waves and tides in the sphere.—**R. W. B. Pearse** : The ultra-violet rum of magnesium hydride II. The bands of the y-lined ultra-violet (γ) system of magnesium ide have been measured in the region λ 2560 to 40. The vibrational analysis shows that this m has no level in common with the previously n α- and β-systems. The rotational structure at characteristic of the $^1S \rightarrow {}^1S$ type of electron ition. Measurements of the isotope effect in two e bands indicate that the emitter is the diatomic cule MgH (or MgH^+), Mg having isotopes of ic weights 24, 25, and 26.—**G. Temple** : The d-order wave equations of the spinning electron. equations are obtained by a simple modification axwell's electrodynamic equations. As in Dirac's y, non-commutative properties of the operators mployed to introduce spin-correction terms into ave-equations and expressions are obtained for ge-density and current-density, together with isation and magnetisation.—**A. V. Hill** : Anaerobic val in muscle.

ysical Society, May 24.—**J. H. Vincent** : Experi-s on magnetostrictive oscillators at radio fre-cies. An account is given of the behaviour of nagnetostrictive oscillators, 6 mm. and 4·5 mm. gth, when placed in a coil in series with the main tion coil of a simple valve-maintained oscillating t. The frequency characteristic of the smaller ator is 540 kc./sec.

ne 14.—**W. Jevons** : The band spectrum of lan-um monoxide : with a preliminary note on onic band spectra of diatomic molecules. The rum has been observed from λ8700 to λ2850, and and-heads (most of them not hitherto recorded) ged into several systems.

PARIS.

ademy of Sciences, May 27.—**Ch. Lallemand** and **évot** : Slow variations of the mean level of the n the French coast. The rise in the sea-level, ed on the French coast for the last three-quarters century, is not due, as had been supposed, to a sinking of the ground, but to astronomical omena of a periodic nature. The total amplitude of the regular oscillation appears to be about 7·5 cm.—**H. Vincent** : The therapeutic results given by a new antistreptococcic serum. Detailed account of clinical results obtained with the new serum.—**André Blondel** : The powers and mutual *hormanances* of non-sinusoidal alternating currents. Suggestion of a new terminology for wattless currents.—**E. Mathias** : Contribution to the study of fulminating material. Discussion of the best means of protecting buildings against globular lightning.—**J. Neyman** : The limit of probability of hypothesis.—**Paul Dubreil** : Some complements to Nœther's theorem.—**Serge Bachvaloff** : The simultaneous deformation of two associated surfaces.—**S. Finikoff** : The congruences of Goursat.—**Georges Durand** : The construction of Cantor-Minkowski in the plane.—**Miron Nicolesco** : A theorem of Pompeiu.—**René Lagrange** : Certain functions associated with Legendre functions.—**Henri Cartan** : The growth of meromorph functions of one or more complex variables.—**J. Le Roux** : Systems of reference with apparent gravitation.—**H. Mineur** : Statistical researches on the solar apex and on the vertex of the distribution of the stellar velocities.—**Alex. Véronnet** : The electronic theory of the ether and of light. The electronic theory, extended to the ether, explains the field not mechanically but electrically. From this theory can be deduced the laws of light, magnetism, and gravitation.—**V. Bjerknes** : The equations of hydrodynamics.—**J. E. Verschaffelt** : Can the Maxwell-Clausius relation be explained without recourse to the principle of Carnot ? Critical discussion of a recent communication (*C.R.* 1929, p. 778) of V. Karpen.—**L. Brüninghaus** : The existence of a conducting state of so-called insulating liquids. Certain liquids (petrol, vaseline oil, crystallised benzene) in thicknesses of the order of 0·5 mm. show a slight conductivity, diminishing with time : this may be attributed to the presence of traces of dissolved water. But for thicknesses of the order of 10 μ a new phenomenon appears. Under a potential difference of from 50 to 110 volts, these insulating liquids suddenly acquire metallic conductivity. The possibility of a short circuit was excluded and there was no pulverisation of the metal.—**Pierre Bricout** : The efficacity of discontinuous electrostatic screens.—**G. Siadbei** : A new use for piezo-electric quartz. An application to chronometry.—**Edmond Rouelle** : The characteristics and stability of ferroresonant circuits (oscillating circuits admitting of coils with iron cores).—**Jean Thibaud** : The possible existence of important exceptions to the principle of selection relative to the total quantic number. The N spectrum of thorium.—**A. Canaud** : The electrolysis of water with alternating current. The hydrogen produced is taken as a measure of the electrolysis. The results of experiments with solutions of potassium, calcium, magnesium, and sodium sulphates are given.—**A. Roux** and **J. Cournot** : The study by means of the X-rays of the internal transformations of the silver-zinc alloys. The effects of annealing, tempering, and reheating after tempering were specially studied : the general conclusions given in an earlier communication, based on physical and micrographic measurements, were confirmed.—**S. Rosenblum** : The fine structure of the magnetic spectrum of the α-rays of thorium C. Use was made in these experiments of the large electromagnet of the Academy of Sciences giving a magnetic field of the order of 36,000 gauss.—**M. Prettre** and **P. Laffitte** : The temperatures of ignition of mixtures of carbon monoxide and air. The precautions taken were the same as those described in a previous paper for mixtures of hydrogen and air. The ignition temperature is not modified by the presence of small proportions of residual burnt gases, but is lowered to

a marked extent by water vapour.—**J. Bougault** and **J. Leboucq**: The action of heat on the allophanic amides. The decomposition by heat (200°-210° C.) of the allophanic amides derived from amines of the aniline type gives ammonia, cyanuric acid, and a symmetrical urea. The allophanates derived from hydrazines behave differently, there is no formation of cyanuric acid, ammonia is produced and there is condensation to a urazol.—**R. Bousset**: The problem of asymmetric synthesis.—**Lespieau** and **Journaud**: 1 : 6-Heptadiine and 1 : 8-nonadiine. These two hydrocarbons are produced by the interaction at ordinary pressure of the sodium derivative of acetylene and trimethylene bromide and pentamethylene bromide respectively. The physical and chemical properties of the two hydrocarbons are given.—**Mme. Pierre Billon-Bardon**: The reduction of diphenylglycidic ether by means of sodium and absolute alcohol.—**Henri Moureu**: The tautomerism of the α-diketones: Study of the states of equilibrium. Methylbenzylglyoxal can be obtained in two tautomeric forms differing markedly in their refractive indices. Starting with either of these, the equilibrium in the presence of a catalyst can be studied by means of the refractive index. The results of the experiments, shown graphically, prove that the same equilibrium point is reached whichever isomer be taken.—**A. Leulier** and **Y. Dreyfuss**: The bromination of 1 : 4-aminophenylarsinic acid.—**R. Fosse, A. Brunel,** and **P. De Graeve**: The quantitative biochemical analysis of allantoin in the presence of urea. Hydrolysis is carried out by means of *Soja hispida*, in presence of ammonium carbonate. The urease destroys the urea and the allantoinase converts the allantoin into allantoic acid.—**Edgar Aubert de la Rue**: The existence of agate and of Iceland spar in the Kerguelen Archipelago.—**Jacques Bourcart** and **Guy Le Villain**: The Acadian of the Moroccan Antiatlas.—**A. Demay**: The Moldanubian (Hercynian chain).—**A. Perrier**: The presence of certain thermophile fungi in farmyard manure and in organic matter undergoing decomposition. A fungus with optimum temperature of growth 40° C. which resists a prolonged exposure to 55° C. is termed thermo-tolerant, reserving the word thermophile for moulds the optimum culture temperature of which is above 50° C. One such mould has been isolated with an optimum culture temperature of 57°-60° C. and resisting several hours' exposure to 72° C.—**V. Ghimpu**: Contribution to the chromosome study of the Acacia.—**G. Mangenot**: The so-called phenomena of aggregation and the arrangement of the vacuoles in conducting cells.—**A. Sartory, R. Sartory,** and **J. Meyer**: A disease of the melon (*Citrullus vulgaris*) caused by a Fusarium and a colour-producing bacterium.—**R. Bonnet** and **Tchang-Hyao-Tchi**: Overfeeding. Experiments on giving a considerable excess over the normal food ration to the rabbit and the pigeon. It was shown that the alimentary canal acted as a regulator of the energy distribution.—**Emile F. Terroine** and **P. Danmanville**: The formation of creatine at the expense of proteid substances.—**Michel Polonovski** and **René Hazard**: The comparative cardiovascular actions of two isomers: tropanol and pseudotropanol.—**A. Fessard** and **H. Laugier**: The form of the electromyogram of voluntary contraction. Oscillographic records.—**Robert Faillie** and **Martinot Lagarde**: Study of the influence of lighting on the precision of movements in the course of professional work. Three different tests were applied to five subjects, and the mean results are given as curves. These show that for feeble illumination a small increase in the light intensity produces a marked improvement in the precision of the movements.—**H. Colin** and **P. Ricard**: Some properties of laminarine from the Laminaria.—**Paul Cristol**: The interpretation of the values for the alkaline reserve of the blood plasma in the course of the keto-acidoses. In the cases of keto-acidosis, normal or high alkaline reserve frequently met with in diabetes, should be regarded as results due to defective technique; the accumulation of acetylacetic acid in the blood causes errors in the analytical method of Van Slyke.—**J. Vellard** and **Miguelote Vianna**: Modifications of the blood coagulation in yellow fever: their importance for the early diagnosis.—**A. Saenz**: The transplacental infection of the guinea-pig by the ictero-hæmorrhagiae spirochæte.

COPENHAGEN.

Royal Danish Academy of Science and Letters

Jan. 25.—**C. Wesenberg-Lund**: Contributions to the biology of *Leukochloridium paradoxum*. This peculiar Trematod larva, living in *Succinea putris*, has been studied for four years, partly in Nature and partly in cultures, some of which are more than four years old.

Feb. 8.—**P. O. Pedersen**: Long retarded echo signals. Discussion of the possibility of obtaining long retarded echo signals of the propagation of radio waves within the terrestrical atmosphere, or by reflection from or by propagation along ionisation bands outside this atmosphere.

Feb. 22.—**Ojvind Winge**: The nature of the sex chromosomes in *Humulus*. The male plant of *Humulus Japonicus* has three X-chromosomes, while the female has two. The difference between the two sexes, thus, is of quantitive nature. In *H. lupulus* the male has one X- and one Y- and the female two X-chromosomes, the Y-chromosomes of the male plant being homologous with the two X-chromosomes of *H. Japonicus*.

Mar. 8.—**Elis Strömgren**: Some classes of orbits in the restricted problem of three bodies (problème restreint). In 1889 and 1892 the Danish Academy set two prize questions, which resulted in the first attempt (v. Haerdtl and Burrau) to solve with the aid of numerical integration such special cases of the problem of three bodies as are not pure problems of perturbation. In 1897 G. H. Darwin published his well-known paper "Periodic Orbits", in which some classes of periodic orbits in the special problem, the "Problème restreint", were studied. In 1913 the problem was again attacked at the Copenhagen Observatory, and the programme—the study of all simple periodic orbits in the problème restreint—has now been carried through. The present paper gives the numerical results for some of the classes of orbits. The whole numerical material is to be published.

Mar. 22.—**Harald Bohr und Börge Jessen**: The distribution of the Riemann ζ-function (1).—**C. Ostenfeld**: A fertile interspecific hybrid in the genus *Polemonium*. *P. mexicanum* and *P. pauciflorum* are two Mexican species, the former rather a slender plant with short blue corollas and transparent tube about 3·5 mm. in length, the latter a coarser plant with fewer and larger flowers, yellowish corolla with reddish tinge and tube about 30 mm. long. *P. mexicanum* ♀ × *P. pauciflorum* ♂ gives an intermediate and uniform F_1, which splits in F_2 and F_3 and is fertile. The reciprocal cross fails, probably because the pollen of *P. mexicanum* is not able to grow down the stigma of *P. pauciflorum* to its ovary.

April 19.—**L. Kolderup Rosenvinge**: Reproduction in the Danish species of *Phyllophora*. The nemathecium of *Phyllophora Brodiæi* does not belong to a parasite (*Actinococcus*), and it is not an organ of the *Phyllophora*-plant; it arises on a sporophyte developing in the sexual shoots from the auxilia

f a procarp, breaks through the surface of the and produces nemathecia. On germination, etraspores of the latter give rise to young plants *Phyllophora*. The nemathecia of *Phyllophora* s are true organs of the species.

y 5.—**C. H. Ostenfeld**: The species of larch x) and their geographical distribution. All the es are found on the northern hemisphere and are, ule, mountain plants; towards the north some of occur at the sea-level. Three of the ten species in North America, the others in Eurasia. Most em have restricted areas of occurrence; only *irica*, *L. dahurica*, and *L. laricina* are widespread. distribution of the various species is given.

GENEVA.

ciety of Physics and Natural History, Mar. 21.—. Gutzeit and Ch. Devaud: A new automatic ratus for titration. The apparatus is based on act that the potentiometric curve of the liquid hich the reaction takes place presents a sharp num at the neutral point, in the case of a strong and a strong base. The arrangement, which also des automatic filling of the graduated burette, ch that the titration is automatically stopped at neutral point.—**E. Briner, P. Schnorf, and R.** r: The ozonation of the gaseous unsaturated ocarbons. The authors have specially studied the ation of those unsaturated hydrocarbons (ethylene, ylene, butylene), which are present in industrial (lighting gas, coke oven gas, gas from oil king). These substances have been submitted to isation, either in solution at a low temperature, the view of the production and study of the ides, or in the diluted gaseous state in the presence ore or less steam, which removes all danger of sion. The yields recorded for the utilisation of e and these hydrocarbons are sufficiently high to a technical interest to the problem studied.—**Parejas**: Geological observations in Corsica (4). ils of the Lias of Corte and the autochtone mulitic of Lozari. The author notes the presence e "brèche du Télégraphe" of Corte of limestone s associated with carbonaceous deposits. These s are identical with those of the zoned limestones he middle Lias of the Chamonix region. The chtone Lutecian of Lozari extends to the north he sea; it is there represented by a coarse grit aining *Nummulites perforatus* and *Discocyclina iaci*.—**E. Rod and G. Tiercy**: The eclipse of the of Nov. 1, 1929, at Geneva. The times of first last contact have been calculated graphically; rst contact will take place at 11.16, Geneva civil the last contact at 13.8. The middle of the se will be at 12.12. At this time 0·18 of the sun's eter will be covered by the moon. Hence at va the eclipse will not be very noticeable.—ercy: Where astronomers and navigators do not ar to have been happy in the choice of a term. author recalls that astronomers and navigators consider the terms 'correction' and 'rate' of a clock as having the same meaning. In y 'correction' and 'rate' have opposite signs, e the word rate (*état*) has the usual signification to it in the ordinary language of business, ce, physics, etc. This confusion appears to arise the fact that astronomers have called the *marche* hronometer the difference between two successive ctions (correction$_1$ − correction$_2$), whilst in ordin-anguage the course of any enterprise is the ence between two successive rates (rate$_1$ − rate$_2$); latter mode of expression is that generally oyed by clockmakers.

MELBOURNE.

Royal Society, April 11.—**C. H. Ostenfeld**: A list of Australian sea-grasses. As a result of the examination of the National herbaria of New South Wales and Victoria and of some recent collections from the eastern States, several interesting additions to the knowledge of the distribution of the sea-grass flora of Australia are listed.—**Isabel C. Cookson**: An account of a crown rot of English walnut trees in Victoria. A crown rot of English walnuts has occurred spasmodically for some years in the north-eastern district of Victoria, the casual organism has been found to be a species of *Phytophthora*, compared by the writer with *P. parasitica* Dastur. It is an intercellular parasite occurring in the phlœm and cambial regions, causing the death of these tissues, and a subsequent separation of the wood and bark. The parasite has been isolated in pure culture, and its life history followed. When inoculated into seedling walnuts, death has resulted, and from their dead tissues the fungus has been re-isolated.

Official Publications Received.

BRITISH.

Wigan and District Mining and Technical College. Opening of Extension by the Rt. Hon. the Viscount Chelmsford, 13th June 1929. Pp. 14+9 plates. (Wigan.)

Journal of the Indian Institute of Science. Vol. 12A, Part 6: i. A Study of the Symbiotic Fungus from the Mysore Lac Insect, by M. Sreenivasaya and S. Mahdihassan; ii. The Golgi Apparatus of Free-living Protozoa, by H. S. Madhava Rao. Pp. 69-77 + 3 plates. (Bangalore.) 12 annas.

Diary of Societies.

FRIDAY, JULY 5.

INSTITUTION OF CIVIL ENGINEERS (Birmingham and District Association), at 8.30 A.M.—Visit to Liverpool to see the Work in connexion with the Mersey Tunnel.

OVERHEAD LINES ASSOCIATION, at 12.15 P.M.—Visit to the Mid-Cheshire Electricity Supply Company.

GEOLOGISTS' ASSOCIATION (in Architectural Theatre, University College, Gower Street), at 7.30.—Christopher T. A. Gaster: Chalk Zones in the Neighbourhood of Shoreham, Brighton, and Newhaven, Sussex. —H. G. Smith: Some Features of Lamprophyres, near Sedbergh, Yorkshire.

SATURDAY, JULY 6.

PHYSICAL SOCIETY (at the University, Birmingham), at 3 P.M.—S. W. J. Smith and A. A. Dee: The Magnetic Analysis of Steels.—T. L. Ibbs and K. E. Grew: Thermal Diffusion at Low Temperatures.—G. Barlow and H. B. Keene: The Damping of Vibrations in Steel Tuning Forks and its Variation with Temperature.—J. Young: The Crystal Structure of Some Carbohydrates.—M. C. Johnson: Note on the Origin of Certain Interatomic Forces.

PHYSIOLOGICAL SOCIETY (in Physiology Laboratory, Oxford), at 3.30.—H. V. Horton: The Reversible Loss of Excitability in Isolated Amphibian Voluntary Muscle.—C. W. Carter and A. N. Drury: Heart Block in Rice-fed Pigeons.—Samson Wright and H. A. Bulman: Physiological Action of X-Rays.—G. P. Crowden and E. Ogden: The Effect of Adrenaline on the Non-protein Nitrogen in the Blood of Decerebrate Cats.—G. Ekehorn: Some Observations on the Concentration of Glomerular Fluid.—Prof. H. E. Roaf: Visual Acuity with Light of Short-wave Lengths.—Prof. R. A. Peters: Observatio upon the Oxygen Consumption of *Colpidium colpodi*.—Demonstration —S. Cooper and J. C. Eccles: Isometrically Recorded Motor Respons in a Mammalian Preparation.—H. M. Carleton: Some Recent Metho in General Histology (Microscopes).—Dr. J. F. Fulton and E. G. Liddell: Chronic Decerebellate Animals.—J. C. Eccles and Sir C. Sherrington: Reflex Summation.—J. C. Eccles: Fluid Electrod suitable for the Mammalian Preparation.—T. Lewis: Standard Colou for estimating Cyanosis in Skin.

MONDAY, JULY 8.

SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (Annual Gener Meeting) (at Municipal College of Technology, Manchester) (and July 9 to 13).

TUESDAY, JULY 9.

SOCIETY OF CHEMICAL INDUSTRY (at Manchester), at 10.15 A.M.—Annu General Meeting.—Dr. A. D. Little: Science and Labour.

SOCIETY FOR THE STUDY OF INEBRIETY (at 11 Chandos Street, W.), at 4. W. McAdam Eccles: Some Gaps in the Study of Inebriety (Presidenti Address).—Sir William Willcox and others: Discussion on The Tox Effects of Methylated Spirits and Impure Forms of Alcohol.

WEDNESDAY, JULY 10.

SOCIETY OF CHEMICAL INDUSTRY (at Manchester), at 10 A.M.—Annu Meeting.—Prof. T. H. Pear: The Human Factor in Industry.—Dr. A. Little: Process Development.

INSTITUTION OF MINING ENGINEERS (at University College, Nottingham), 11 A.M.—General Meeting.—Dr. W. Hancock, A. G. R. Whitehous and Dr. J. S. Haldane: The Salts lost by Sweating owing to High Ai temperatures (Sixteenth Report to the Committee on The Control Atmospheric Conditions in Hot and Deep Mines).—Dr. J. S. Haldan Work of the Committee of the Institution of Mining Engineers The Control of Atmospheric Conditions in Hot and Deep Mines. The following papers will be submitted for further discussion: W. S. Cooke and I. C. F. Statham: The Flow of Air at Bends and Straight Airways (Sixth Report of the Midland Institute Committ on the Ventilation of Mines).—Dr. T. David Jones: Spontaneous Co bustion in North Staffordshire. Part II. A Record of Analyses Air-samples taken during the Combating of a Fire.—Dr. T. F. Wal Electro-magnetic Testing of Wire Ropes.—2.15.—The General Meeti will be resumed.—3.30.—The General Meeting will be closed.

TUESDAY, JULY 16.

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section).—Visit to t Works of Messrs. J. S. Fry and Sons, Ltd., at Somerdale, near Bristo

PUBLIC LECTURE.

TUESDAY, JULY 16.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, at 5.—Sir Thom Lewis: Observations Relating to the Mechanism of Raynaud Disease (Victor Horsley Memorial Lecture).

CONFERENCES.

JULY 10 TO 12.

ELECTRICAL ASSOCIATION FOR WOMEN (at North-East Coast Exhibitio Newcastle-upon-Tyne).—Fourth Annual Conference.

JULY 12 TO 14.

MIND ASSOCIATION (Annual Meeting) (jointly with Aristotelian Societ (at University College, Nottingham).

Friday, July 12, at 8 P.M.—Prof. F. Granger: Probability and Paradox.

Saturday, July 13, at 10 A.M.—Prof. G. E. Moore and H. W. B. Josep Indirect Knowledge.

At 2.—Prof. J. Laird, C. E. M. Joad, and Miss L. S. Stebbing: T Present Position of Realism.

At 8 P.M.—J. D. Mabbott, H. H. Price, and G. Ryle: Negation.

Sunday, July 14, at 2.—Prof. G. Dawes Hicks, Prof. B. Edgell, and Pr G. C. Field: Immediate Experience.

At 8 P.M.—Address.

JULY 13 TO 20.

ROYAL SANITARY INSTITUTE (at Sheffield).

In Sections devoted to Preventive Medicine, Architecture and Engi eering, Maternity and Child Welfare (including School Hygiene), Hygie of Food, Hygiene in Industry, Veterinary Hygiene, Representatives Sanitary Authorities, National Health Insurance Services, Medic Officers of Health, Engineers and Surveyors, Sanitary Inspecto Health Visitors (including Personal and Domestic Hygiene).

No. 3115, Vol. 124]

Mineralogy at Cambridge.

THE position of mineralogy in the studies of the University of Cambridge is the subject of a report by a syndicate appointed by a Grace of the Senate dated May 12, 1928, in accordance with a recommendation made on the election, for a term of five years, of the present professor of mineralogy in 1926. The Syndicate held five meetings, at some of which the professor of mineralogy was present by invitation. The members also had before them a memorandum on the history and present position of the Department by the professor of mineralogy (published as an appendix to the report), and a memorandum on the study of structural crystallography in Great Britain and on the Continent prepared by the University lecturer in that subject. The University reader in petrology was a member of the Syndicate. The main recommendations which have been put forward were reported in a note in NATURE of May 18, p. 780.

The foundation of the Woodwardian professorship provided for the teaching and development of mineralogy as well as geology, but apparently not to the satisfaction of a great enthusiast, Edward Daniel Clarke, at whose instance the present chair of mineralogy was founded in 1808. This originated the separation of geology and mineralogy, which resulted in their representation as independent subjects in the Tripos. Under Clarke's successors, however, crystallography became the main subject taught by the professors of mineralogy. Petrology was practically ignored, and when the study of thin sections of rocks with the polarizing microscope opened up great possibilities in this branch of the science, it was left to the department of geology to develop the new method. Thus an important part of mineralogy came again under the Woodwardian professor and has remained separated from the department of mineralogy. This separation, the Syndicate truly remarks, has adversely affected both studies.

More recently, the great advance in the development of crystallography due to the X-ray analysis of crystal structure has made crystallography still more dominant in the department of mineralogy and further accentuated its separation from petrology and economic mineralogy. The Syndicate believes that the future development of crystallography "lies mainly in fields bordering upon both physics and chemistry". It is convinced that crystallography and mineralogy (and petrology) cannot be adequately developed in one

department, but it does not think that they can be separately catered for in existing departments. It accordingly recommends a new grouping of the subjects, for which the department of mineralogy is to be replaced by two departments, crystallography being taught in one, and mineralogy and petrology in the other. It is recommended that the department of mineralogy and petrology should be in "the closest possible relation with the department of geology" and that "the teaching of such crystallography and crystal physics as is required by students of mineralogy and petrology should be provided by the department of crystallography". The successful carrying out of these particular recommendations will depend mainly on the cordial co-operation of the three professors concerned. As regards the staffing of the two departments, the minimum establishment proposed—a professor, lecturer, and demonstrator in each—is actually less than the number at present engaged in teaching mineralogy, crystallography, and petrology in the University. The only innovation proposed is the foundation of a professorship in place of the post at present occupied by the University reader in petrology.

For the success of the new departments the Syndicate thinks it essential that the subjects taught in both shall be separate subjects in Part I. of the Natural Sciences Tripos. These separate subjects are, however, not regarded as of sufficient importance to rank equally with the existing subjects in that examination, yet they are too important to be crowded into the already overburdened curriculum of geology, physics, and chemistry. The solution offered is to create 'half-subjects'. Under this scheme crystallography, the scope of which is outlined, is to be an independent subject but to carry a smaller maximum of marks than the existing subjects: mineralogy and petrology either to be treated similarly or—at the students' option—to be allowed to be an alternative to palæontology in the existing subject of geology. Thus a student offering chemistry and physics could take crystallography without mineralogy, while students offering geology could omit palæontology and take mineralogy and petrology "and such crystallography and crystal physics as is required", or they could include palæontology and take both mineralogy and petrology and also crystallography, and one (or more) of the existing subjects.

Finally, the Syndicate has considered accommodation. The creation of an additional department demands a new building, and the recommendation is to build new laboratories and a museum f mineralogy and petrology adjoining and commun cating with the Sedgwick Museum. Crystall graphy could then be adequately developed in t rooms at present occupied by mineralogy. Th would involve considerable capital expenditur and, in a note to the report, the Financial Boa points out that this "could only be provided at t expense of existing University activities". It ma be thought that in recommending a plan t adoption of which depends on the provision of new building, the Syndicate has doomed its repo to rejection. But the memorandum on accor modation submitted by the professor of mineralog and the remarks of the Syndicate on the lack laboratories for the study of petrology in the Sed wick Museum, are convincing proof that the prese accommodation is lamentably inadequate and u worthy of the University. Proper accommodati to allow the development of crystallograph mineralogy, and petrology has been an urgent ne for the past ten years, and the Syndicate has do good service by bringing this need prominent to the notice of the University.

If the means to meet this need cannot be foun the main recommendations of the Syndicate f the creation of two departments will inevitably postponed. There would remain the possibility the suggested changes in the Natural Scienc Tripos, which do not actually necessitate t splitting up of the present department of mine alogy. The introduction of these changes mig be sufficient to effect that close co-operation b tween mineralogy and geology which the Syn cate desires, and then, as is remarked, "the fa that [mineralogy and petrology] are taught in sep rate departments might be no more than inconvenience". With suitable modifications the scheme of lectures, students of physics a chemistry could take crystallography as a su ject without the necessity of learning descripti mineralogy.

The report was discussed during last term by t appropriate Boards in the University, and t results of their deliberations will be awaited wi interest. The adoption of a definite policy wi regard to mineralogy cannot long be postpone as any changes decided on must take effe from 1931, when the chair of mineralogy will vacated by the present professor, who succeed W. J. Lewis in 1926 after thirty-one years' voted service to the department over which two immediate predecessors had ruled for alm a century.

Industrial Catalysis.

tic Processes in Applied Chemistry. By f. T. P. Hilditch. (Monographs on Applied mistry, Vol. 2.) Pp. xx + 360. (London: pman and Hall, Ltd., 1929.) 16*s.* net.

he field of fiction it is usual to find an occa- onal volume in publishers' announcements ed as the book of the year. Such title might, r opinion, be applied with justice to Prof. ch's latest production in the field of chem- Eminently readable, lucid, accurate, and ritative, and in addition well presented by the her, it comes near to realising our ideal of an advanced text-book should be, having in always that it is written to promote the ation of science in industry.

ough the recognition of catalytic action is more a century old, it is only during the last thirty ty years that the subject has received detailed , whilst its present status as the fashionable f applied chemistry is only a post-War growth. d, as Hilditch points out, until about 1920–25, was a distinct conflict of opinion as to the anism by which a solid catalyst effected cal changes in solids or liquids. The rival were the physical, which assumes the property centrating gases in a layer at solid surfaces, e chemical or intermediate compound theory. t the latter is generally accepted, there is, as s, truth in both theories, and to-day the ists have come to the conclusion that the tion processes concerned in catalysis are ioned by forces indistinguishable from chemi- finity and are mainly concerned with uni- ular layers. At the same time, the chemists come to appreciate that an association of the ic molecules with the solid catalyst occurs, is at least equal in general character to, for ple, the association between hydrogen and a st.

is the process preparatory to the chemical e is now fully understood and there remains vestigate the next stage, how the energy ary to effect the change is applied.

book starts with a classified list of processes f products, making easy reference for those sted in a particular reaction. After a brief on the general development, there comes a lear and concise chapter on the theoretical s of catalysis at solid surfaces, which goes on l with catalyst poisons and catalyst stimu- and is followed by a special section on the of enzymes, the study of which has done much to promote the understanding of catalytic action.

The more technical section, after an introductory chapter, deals in turn with the various industrial applications of the principles of catalysis. Necessarily, the reference to any one process is brief, but it is fully adequate to cover the principles and special problems involved, and the description is all the better for being concise and not cumbered by lengthy extracts from patent specifications, which, as we are at last beginning to learn, are far from being a model of scientific literature or accuracy.

Amongst the subjects considered are the production of hydrogen, methane, methyl alcohol, etc., from water gas, and the synthesis of ammonia, cyanamide and urea, achievements which have resulted in the erection of plants the capital cost of which runs into tens of millions and will change the whole future of agriculture. The conversion of ammonia into nitric acid, by means of platinum or ferric oxide plus bismuth catalysts, will soon make the older methods for the manufacture of this acid obsolete, and cheap nitric acid may have much wider application than at present.

Contact sulphuric acid is already an old catalytic industry, but there is no end to invention in this field. We pass over chlorine manufacture and coal gas purification to the new field of synthetic organic aldehydes and ketones obtained by the dehydrogenation of alcohols. Such products are not only valuable solvents, but they are the starting-points of further syntheses, such as that of acetic acid, which as cellulose acetate becomes the raw material for a synthetic textile which has already begun to effect a social revolution.

Hydrogenation was one of the earliest of successful catalytic processes and bid fair at one time to effect a revolution in the fat industry; it is now being extended to deal with benzenoid compounds. Active charcoal as a catalyst is still in its infancy—it is a direction in which we prophesy great developments.

A considerable section is devoted to fermentation processes, which now involve the production on an ever-increasing scale of such substances as glycerine, acetic, butyric and lactic acids; of butyl alcohol and acetone, as well as vinegar, amyl alcohol and ordinary alcohol.

We have indicated the scope of the book, partly with the object of showing to what extent the principles of catalysis are being applied in industry to produce substances of ever-growing importance, which a few years ago were scarcely of interest outside the laboratory. It is in this direction that

the potentialities of the subject are greatest, and within the next ten years we may confidently look for astounding progress. Prof. Hilditch's book may well form the 'Bradshaw' for such journeyings into the future, and we believe it will be found to be equally trustworthy. E. F. ARMSTRONG.

Early Science in the United States.

History of the Sheffield Scientific School of Yale University, 1846–1922. By Prof. Russell H. Chittenden. Vol. 1. Pp. ix + 298 + 36 plates. Vol. 2. Pp. x + 299-610 + 57 plates. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1928.) 45*s*. net.

THESE two large and handsome volumes on the scientific department of Yale University begin with an interesting survey of the position of science in education in the first half of the nineteenth century. Dr. Chittenden gives pride of place to British scientific workers, mentioning Humphry Davy, Faraday, Dalton, Bell, Herschel, and Lyell before he passes on to the French. But when we turn to the provision of laboratories and to the place taken by science in the public education of the different countries, the story is different. France and Germany—the former on the mathematical and the latter on the chemical side—were far in advance of Britain, and it may be doubted whether the leeway has yet been made up completely. The list given on p. 18 of institutions for higher scientific and technical training in Paris in the 'thirties is amazing, and at the same time one had the famous laboratories of Liebig at Giessen and Munich attracting chemical students from all over the world. England was from that point of view far in arrear and long remained so.

It is a curious and notable fact that the United States, the youngest branch of the Western family, and endowed with the richest supply of untapped natural resources, should have clung to the most antiquated methods of higher education and been most reluctant to alter them. "There was a deep-seated aversion", Dr. Chittenden tells us, "to new ideas, especially if the latter threatened to diminish in any degree the amount of time available for the dead languages, and science, so far as it was understood, was considered of relatively small importance, and to have little educational value." He has analysed the old course of instruction at Yale, Harvard, and Williams College for the year 1845, and shows the enormous preponderance of Latin and Greek, with some mathematics, and an occasional dash of botany, chemistry, or geology.

The change, so far as Yale is concerned, w mainly due to Benjamin Silliman, who was appoint professor of chemistry at Yale in 1802. Imme ately after his appointment he was allowed perio of absence to visit other places where he could me men and study institutions likely to help him in work. In America at that time Philadelphia w the most advanced centre of scientific knowled especially of chemistry. Benjamin Franklin h founded there in 1727 both the American Phi sophical Society and also the University of Penns vania, and at the latter place Benjamin Rush, "t father of chemistry in America", was teachin There also Silliman met Priestley, who had fl from England on political grounds. But he we on to Europe and made friends in England wi Sir Humphry Davy and Sir David Brewster, b sides collecting physical and chemical apparat and the latest books on scientific subjects. Th prepared, he returned for his long period of profe sorial work at Yale. Silliman held his post wi increasing success up to 1845, and was undoubted the founder on the spiritual side of the Yale Scho of Science, to which shortly after his retirement adequate material home was provided by the mu ficence of a railway constructor named Sheffie from whom it takes the title of the 'Sheffie Scientific School of Yale University'.

The years, however, of Silliman's professorsh were passed amid the hardships of inadequate fun and cramped quarters. For fifteen years he had laboratory only a part of the cellar of the Lyceu building, a space with raised seats and a lectu table for experiments. Yet even here he manag to do work which placed him in the front rank of t American chemists of his day, and in those sa years Olmsted succeeded at Yale in making t first observation of the return of Halley's comet, 1835, and Morse, a graduate of Yale, designed electric telegraph.

In 1846, the year following Silliman's retireme from teaching, though he still remained active other spheres, the Smithsonian Institution w created by Act of Congress under the terms of t will of "James Smithson, of England, for the crease and diffusion of knowledge among men A decade later, Mr. Sheffield came on the scene wi money for buildings and endowment, and the det mination to give the institution a practical turn. railway engineer he provided amply for engineerin North, Silliman's first colleague, represented ag cultural chemistry, and the volumes before us scribe all the other branches which afterwards gr up and the leading men who have adorned them

ne second volume, with its plates representing e six or eight magnificent buildings devoted to rent branches of science and called after some thy benefactor or distinguished teacher, is uent testimony to the noble emulation of the rican citizen when his sympathies are once sed. Yale and its school of science have been fied of their sons. F. S. M.

Treatises on Astronomy.

Faculté des Sciences de Paris : Cours d'astronomie. Tome 3 : *Astrophysique.* Par Prof. Jean osler. Pp. v + 723 + 47 planches. (Paris : ermann et Cie, 1928.) 140 francs.

Trattato di astronomia siderale. Per Prof. iuseppe Armellini. Vol. 1 : *Parte generale.* p. xi + 94. (Bologna : Nicola Zanichelli, 1928.) 5 lire.

HE problems presented by the need for specialisation in science have been evident long igh to become a commonplace, but recent years e seen them grow rapidly more acute and tent. In physics, for example, the yawning grows daily more apparent, and, by a curious dox, the more desperate the efforts made to find ifying scheme for all physical phenomena, the e extravagant and impossible become the deds on a single mind attempting to cope with he problems of the subject. How a man like ate Lord Rayleigh, if spared beyond the allotted , would have kept abreast of modern develop-ts, is uncertain, though he would doubtless have d some way of doing so. What seems quite r is that, without going outside the familiar e of his own thought, he could have continued nrich the science by invaluable contributions of acteristic quality. As new fields are added, the do not become less worthy of cultivation. The ger of neglect must be avoided, even by recogng the need for distinct classes among the andmen.

, however, this be so in the case of a fundamental relatively self-contained science like physics ch yet has its debts as well as its gifts to other nces), what is to be said of astronomy, which vs fresh nourishment from every scientific er ? So late as the beginning of this century, it still possible for a young astronomer, starting with a fair stock of mathematical and physical wledge, to keep pace with the current literature is subject as it appeared. No doubt he might me professionally immersed in the technicalities ay) meridian astronomy and neglect to follow the advances in solar physics or dynamical astronomy. He may even have been wise to concentrate all his attention on one line of research. But such a course was a matter of his own taste and concern, not forced upon him. To-day the position is undeniably changed, and even the most omnivorous, after wading through all the courses of a meal no less lavish than formerly, can scarcely be expected to do equal justice to the new dish provided by atomic physics. However willing the spirit, the flesh is weak. A division of interest is inevitable, and all that is now possible is to mitigate so far as possible the evil effects of isolation. The changing circumstances will be accepted reluctantly by some who cherish breadth of outlook, but now *il faut cultiver nos jardins.*

With all this has gone a certain change in astronomical literature. Thirty years ago and less, the young astronomer had little in the way of books (with such notable exceptions as Chauvenet) to help him. He had to plunge into the sea of original papers for what he wanted, and it was good for him. The trained astronomer, brought up in this way, did not feel the want, but the absence of suitable books would have proved a distinct difficulty in establishing an academic course in astronomy similar to those provided for the study of physics.

Of course, there have long been books on astronomy which might be classed as text-books or popular works according as the didactic purpose or popular interest was predominant, but the serious student did not look to them for instruction. Among the more eminent members of the class may be recalled Laplace's " Systéme du Monde ", still famous for the germ it contains of modern theories of cosmogony. Sir John Herschel's " Outlines of Astronomy " is another example, and Newcomb's " Popular Astronomy " yet another, still kept alive by repeated revision. All these, and doubtless others, had notable qualities, but they stand out from a general poverty for which there were reasons. A work intended for the serious student commanded a market too small to be attractive. The professional astronomer, on the other hand, was generally too fully occupied to cater for the popular taste ; to have done so was apt to be frowned upon as a dereliction of duty. But times are changing, and as the subject matter of astronomy becomes enlarged, it is recognised more clearly that an endeavour to place the results of research in an intelligible form before a wide public has not merely an excuse but is a positive duty. The stream of original work grows no less, but convenient and orderly presentments of its results appear with growing and welcome frequency.

(1) Something of this line of thought is suggested by the works under review. Prof. Bosler's book on astrophysics appears as the third volume of a course on astronomy, of which the first two volumes contain a treatise on spherical and practical astronomy by Prof. Andoyer and M. Lambert. Like these, it had its origin in lectures delivered at the Sorbonne, and it forms in a sense a natural sequel dealing with the newer branch of the science, but it can be treated as a quite independent work. It is a little difficult to classify under the head of a text-book, popular handbook, or work of reference, because it has something of the qualities of all three. As a text-book based on academic lectures, it puts into the hand of the student an adequate introduction to the subject of astrophysics. But the general reader, and in particular the amateur astronomer, who is no dismayed by an occasional mathematical formula, will find the descriptive matter relieved by well-chosen illustrations finely reproduced. The references to recent literature are copious but do not pretend to be exhaustive. This will not prevent the book from being very useful to the working astronomer, at least to those whose work lies in other fields.

Prof. Bosler's book is too long for detailed discussion, but a general idea of its contents can be given. After an introductory section on instruments and methods, the work is divided into three parts, each of about two hundred pages in length. These are devoted respectively to solar physics, the physical characteristics of the members of the solar system, including comets, and to the stars and nebulæ. Thus it is to the solar system, which can be studied in fuller detail, that the greater amount of attention is given. But the space allotted to stellar problems is sufficient for the presentation of the main lines of current thought in a rapidly growing subject. The full indexes provided will greatly assist reference to the contents of a bulky volume.

(2) By a coincidence which in itself illustrates the new tendency in the form of astronomical literature suggested above, the first volume of a treatise on sidereal astronomy, by Prof. G. Armellini, appears at the same time as Prof. Bosler's work. This contains a general description of the sky, followed by a discussion of stellar photometry and spectroscopy. A second volume will be devoted mainly to the physical constitution and evolution of the stars, and a third to stellar statistics and the constitution of the universe. In method of treatment and style of production there is considerable resemblance between the work of the two authors, and in bulk the Italian treatise when complete bids fair to exceed the single French volume. Naturally, on several topi the two will overlap and afford an interesting cor parison, but the predominant place assigned by Pro Bosler to the solar system will ensure their ind pendent value on complementary lines. The appea ance of Prof. Armellini's concluding volumes will anticipated with interest, and will give a more co venient opportunity of reviewing his work when can be seen as a whole. H. C. P.

Vital Rays.

Zellteilung und Strahlung. Von Dr. T. Reiter ur Dr. D. Gábor. (Herausgegeben von der Zentra stelle für wissenschaftlich-technische Forschung arbeiten des Siemens-Konzerns.) Pp. iv + 184 3 Tafeln. (Berlin: Julius Springer, 1928.) n.

IT is now several years since Gurwitsch claime that growing roots emit some sort of influen which induces cell division in a neighbouring ro properly oriented, that is, with its axis a prolongatio of the axis of the growing root. The claim seeme improbable, and many misconceptions existe regarding the experimental work on which it wa based and the nature of the claim. But the pe vasiveness of various kinds of radiation has sinc been shown by physicists, and the possibility tha various types of radiation (in addition to those light-producing organs) can arise in the tissues organisms must now be faced. Gurwitsch an his co-workers have extended his results, an confirmatory experiments have been made b Wagner, Magrou, and others. There is thus considerable body of experimental work bearin on this subject, although Gurwitsch's theory ' mitogenetic rays ' has been adversely criticise by Guttenberg and others.

Many of Gurwitsch's experiments were don with onion bulbs and their roots, but these hypo thetical rays have also been found to emanate fro stem tips and other tissues, yeast cells, the mace ated bases of onion bulbs, the eggs of amphibian the heads of tadpoles living or macerated, an various other sources. As regards roots, they a supposed to arise not from the meristematic zon but from the base, and to pass out at the tip of th root because of internal reflection at its surfac Narcosis with chloral hydrate is supposed to inhib the production of these rays, and just as ligh production in organisms is assumed to be due t a reaction between luciferin and luciferase, Gurwitsch assumes that these rays arise whe ' mitotin ', which is killed by heat, unites wit ' mitotase ', which survives a temperature

It has since been claimed that in full-grown nals only the blood produces these rays, and e recently that the tissues of malignant tumours t them.

rom physical experiments it is concluded that rays can undergo reflection, refraction, and raction, like the ultra-violet, and that the wave- gth is about 190-230 $\mu\mu$. Using experimentally duced rays of the same wave-length for com- ison, it is claimed that onion roots are 250 times e sensitive to the 'mitogenetic rays' than a tographic plate.

n the work of Reiter and Gábor, many of these otheses and conclusions receive support. They d Gurwitsch's method of counting the number lividing cells on the side of the root exposed to 'rays' and comparing it with that on the xposed side, but they appear to have used nly cross-sections while Gurwitsch used longi- inal sections of the exposed roots. Their re- rch apparatus and methods are described in ail, so it should be possible to repeat the ex- iments. They attempt a detailed mathematical lysis of the normal growth zones and cell- ision cycles of a root meristem before taking the study of 'induction effects'. They con- r that the term 'mitogenetic rays' takes too row a view of their nature and effect, and suggest t such rays when emitted by biological objects uld be known as Gurwitsch rays.

The experimental results of Reiter and Gábor given in detail, and a few of their conclusions y be mentioned. They confirm the conclusion Gurwitsch that an 'induction effect' may be duced on onion roots by various biological ects, and that this is due to rays from various ng or pulped tissues, while non-growing (*aus- achsenen*) tissues do not show the effect. ignant tumours produce the 'rays', but benign ours do not. There is some evidence that the s affect a photographic plate, but this requires firmation.

Macerated onion bulb tissue produces the radia- only in light, while onion bulbs, tadpoles, and ignant tumours produce it also in darkness. nochromatic light of wave-length about 340 $\mu\mu$ duces the induction effect, which is not so strong n rays of 280 $\mu\mu$. Acceleration and retardation cts are obtained with amphibian eggs and larvæ subjection to monochromatic ultra-violet light, effects varying with the wave-length and the of the animal. In certain cases radiation of e-length 334 $\mu\mu$ caused the parthenogenetic elopment of amphibian eggs.

These and similar results, in which it appears to be possible to treat the radiations from certain active tissues as ultra-violet rays are used in experiment, opens the whole question of the production of radiations by living tissues or substances, a hypothesis which, if substantiated, would have far-reaching effects. Haberlandt (*Biolog. Zentbl.*, Bd. 49, Heft 4) has recently published experiments which he believes support his view that the stimulus to mitosis has a chemical basis, rather than a physical one, in the supposed Gurwitsch rays. It is possible that these views are complementary, both containing some element of truth.

Our Bookshelf.

Tables annuelles de constantes et données numériques de chimie, de physique, de biologie et de technologie. Publiées sous le patronage de l'Union de Chimie pure et appliquée par le Comité international nommé par le VII^e^ Congrès de Chimie appliquée (Londres, 2 juin 1909). Vol. 6: *Années 1923–1924.* Première partie. Pp. xxxiv + 679. Deuxième partie. Pp. xxix + 681-1675. (Paris: Gauthier-Villars et Cie; New York: McGraw-Hill Book Co., Inc., 1927–1928.) Paper, 530 fr.; cloth, 610 fr.; 25 dollars.

THESE two books form Volume 6 of the now well-known "Annual Tables", published under the auspices of the Union of Pure and Applied Chemistry. During the War, the annual nature of the publication became a misnomer, but the arrears are gradually being overtaken, and the present volumes contain the data for 1923 and 1924. It is a sign of the increasing output of scientific research that they occupy as much space as was required for the data of the previous three years.

The object of the tables is to collect together all numerical data published during the period covered by the volume, and this ambition is, to a very high degree, fulfilled. Some forty collaborators are employed, and they search nearly 500 publications, so that very little can escape their net. This net is, in any case, spread very wide. The tables do not restrict themselves entirely to new experimental data; such numerical quantities as schemes of energy levels in atoms (which rely on previous measurements of critical potentials and of spectra) are included, as also are calculated tables for determining the inductances of coils. Short statements of the conclusions drawn by investigators from their measurements are also included, and frequently add considerably to the value of the work.

Now that the series has reached Volume 6, the search for a determination of a constant occupies considerable time, and users of the tables will be grateful for the promise made to produce an index covering Vols. 1-5.

The contents and arrangement of the present volumes are very similar to those of previous years, but an innovation is the translation into English

of all tables and explanatory matter in the sections on metallurgy and engineering. New sections are also added to deal with photography, with wireless telegraphy and related subjects, and with geophysics. The latter in particular is quite a long section and, like the one on biological measurements, will present in convenient form a mass of data which the non-specialist would find difficult to discover without some such help as is afforded by these tables.

Several of the sections have also been issued separately. J. H. A.

The Book of Remarkable Machinery. By Ellison Hawks. Pp. 296+40 plates. (London, Bombay and Sydney: George G. Harrap and Co., Ltd., 1928.) 7*s.* 6*d.* net.

THE writing of books on modern machinery suitable for boys of a mechanical turn of mind, or for others wishing to know something of the marvels effected by invention, is a difficult problem. Descriptions of new machinery contained in the technical journals often run to considerable length and are accompanied by complicated drawings, absolutely necessary, but requiring the closest attention of an experienced engineer. To attempt to compress into one book descriptions of many machines, ranging from steam engines to printing machines, from machine tools to toffee-wrapping machines, is to undertake a task which is bound to lead to criticism.

Mr. Hawks, however, has been fairly successful in initiating us into some of the mysteries of the forge and factory, and with a fine set of illustrations he has given some explanations which can be readily followed. In other cases the matter is too brief to be of much value, and such statements as that on p. 58, where we are told that the steam from a triple expansion engine exhausts into the condenser at 8 lb. per sq. in., and that on p. 131, that a steel rod 1 in. square will withstand a stretching strain of 150 tons, while a cast-iron bar of similar dimensions will withstand a strain of only 20-30 tons, are examples of the errors one unfortunately finds only too often in popular books on engineering. In such books the matter should be accurate, the explanation clear, and the treatment full enough for its purpose.

Through the Apennines and the Lands of the Abruzzi: Landscape and Peasant Life. Described and drawn by Estella Canziani. Pp. xiv+339+24 plates. (Cambridge: W. Heffer and Sons, Ltd.; London: Simpkin Marshall, Ltd., 1928.) 25*s.* net.

IN the last resort it would be difficult to decide whether the award of merit should go to Miss Canziani's paintings or her letterpress in this delightful account of a visit to the Abruzzi just before the War. Both alike are a spirited and detailed record of a primitive culture which no longer survives intact in post-War conditions. When Miss Canziani visited the country she was warned that it was not safe owing to brigandage. Though she did not encounter that peril, the attitude of the peasants at times seems alarming, to the reader at least, even if Miss Canziani takes it calmly enough.

This, however, and the discomforts, even hardships, of her journey are not matters upon which the author dwells. Her interest lies in the customs and beliefs of the people of this most primitive area of Italy. If it were not for the names of the saints and the prominent position held by the parish priest, it would be difficult to believe this a Christian country. Virtually, indeed, it is as pagan as any part of Africa over which Christianity has done no more than spread a veneer. Take, for example, the festival of Domenico, when the Serpari, descendants of Circe, who handle snakes with impunity, cast serpents in hundreds on the image of the saint as it is carried through Cocullo. This, perhaps, is extreme, but it is not atypical. The strength and at the same time the rational character of the belief in the were wolf is indicated by the statement that those who are about to become were wolves shut up their own sheep for protection before the change to the wolf form takes place. Witches of course abound, and charms against the evil eye are everywhere. Miss Canziani's work is a valuable contribution to European folklore, which will need prolonged study before its interest is exhausted.

Elements of Geophysics: as applied to Explorations for Minerals, Oil, and Gas. By Dr. Richard Ambronn. Translated by Dr. Margaret C. Cobb. Pp. xi+372. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1928.) 25*s.* net.

PROBABLY at the present time there is no one competent to write a really good text-book on applied geophysics, but the strong demand for information on the subject has stimulated the production of many books, which fall short of the ideal in very different degrees. Dr. Ambronn's work is perhaps nearer perfection than most, though still very far off. Extreme sketchiness of treatment is inevitable when the attempt is made to deal with the historical, theoretical, and instrumental sides of so wide a subject in 284 pages of text. The author has clearly endeavoured, however, to master his subject and to present it from a scientific point of view, without any axe to grind or any special methods to advocate. The extent of his reading is indicated by the fact that more than sixty pages of the book are occupied by a list of references to authors; judging from the section of this literature known to the reviewer, half of these references might have been omitted with advantage.

It will be long before this great material is properly digested and presented in the form best suited for practical purposes, and the author has not made any very marked step in this direction, though his work may facilitate the process when undertaken in the future by himself or others. The book, however, is likely to have a wide sale among commercial geologists, and justifiably, for there can be few who will fail to glean some useful information from its pages.

Letters to the Editor.

agnetostriction of Diamagnetic Substances in Strong Magnetic Fields.

HE change in shape of a body, when magnetised, be accounted for by two causes. First the sses produced by the magnetic forces act on the netic poles of the magnetised body. This effect, ch we shall call the *classical magnetostriction*, is in ven magnetic field completely determined by the netic susceptibility and the elastic constants of body. In general it will result in a contraction liamagnetic substances and an expansion for para-netic ones. The classical magnetostriction is very ll even for a strongly diamagnetic substance bismuth, where $\delta l/l$ in a field of 300 kilogauss is $1{\cdot}3 \times 10^{-6}$. It is evident that the discovery of an ct of this order would amount to a verification of classical theory of magnetisation and would afford ew information on the property of the substance. n the other hand, in a sufficiently strong magnetic we must expect another phenomenon to happen, ely, an observable change of the shape of the body ch is due to the distortion produced by the field he binding forces between the atoms. This we l call the *atomic magnetostriction*. After the modern ure (Heitler and London) of the homopolar binding es which are essentially of an electrodynamical in, such an atomic magnetostriction must occur netals and other homopolar substances. . The tion is only of the magnitude of the phenomena, ch probably must be small as it has not yet been rved in dia- or para-magnetic substances in weak netic fields.

o find whether such magnetostriction occurs in ng magnetic fields, such as are available in our ratory (*Proc. Roy. Soc.*, **115**, p. 568; 1927), a ial method has to be developed, since the field be produced only for a very short time, during ch the experiment has to be performed. We were essful in devising a method which enabled us to rve changes of length of the order of 10^{-7} occurring rod, placed in the coil parallel to the lines of netic force, the duration of the field being about ndredth of a second and its magnitude up to kilogauss. This method proved to be very rate, since, when the experiment is performed in hundredth of a second, the disturbances produced ccidental thermal variation in length of the rod negligible.

he first substance which was investigated was an ded bismuth rod, and it showed a small con-ion which was only slightly larger than that ex-ed on the classical magnetostriction. But when ismuth rod was grown in a crystal a larger effect easily observed, which could be due only to the ic magnetostriction. A more detailed investiga-showed that, when the trigonal axis was parallel he field the rod expanded; when the axis was endicular to the field the rod contracted. The raction and expansion in the same magnetic field ractically equal, so that in an extruded poly-alline rod they compensate each other, and this nts for the absence of the effect as observed with od. We were also able to trace an atomic magneto-ion in other diamagnetic substances besides bis-, but the effect was about ten times smaller and more difficult to study. We have therefore chosen bismuth as the first to be studied more carefully. The experiments are still in progress, but it seems clear that at room temperature the contraction and elongation vary according to a square law with the field, and in a field of 300 kilogauss the length changes by 5×10^{-5} (larger than is observed in ferromagnetic substances). The temperature has a strong effect, and at the temperature of liquid nitrogen the atomic magnetostriction increases several times.

These results explain why the previous attempts to find magnetostriction in bismuth failed (E. Van Aubel, *Phys. Rev.*, **16**, 60; 1903). In this experiment the largest field used was only 3 kilogauss, so that even with a crystal of bismuth the magnetostriction will be only 5×10^{-9}, but as actually polycrystalline rods were used, the effect will be only of the order of 10^{-10}, and this is too small to be measured.

The general picture of the phenomenon appears to be as follows. The cell of a bismuth lattice is very similar to a cube slightly pulled out along one of its long diagonals, which coincides in direction with the trigonal axis. In a magnetic field apparently the cube becomes still more stretched in the same direction.

From the general theory of magnetostriction (Helmholtz, *Ann. de Phys.*, **13**, 385; 1881) we must necessarily expect that such a deformation of the lattice if produced by pressure will result in an increase of the diamagnetic susceptibility perpendicular to the crystal axis and in a decrease along the axis.

The main physical interest of the phenomenon is that it may conceivably throw more light on the nature of the homopolar bonds. At present, from the general aspects of the phenomenon in bismuth, it is probable that under the influence of the magnetic field the bonds between the atoms which lie farther apart weaken, whilst those of the closer atoms are strengthened. If this view is correct, we must expect to observe larger atomic magnetostriction in the substances where the atoms are not symmetrically bound, such as tin, tellurium, graphite, and others.

A New X-ray Effect.

IT is a remarkable but as yet imperfectly understood fact that crystalline graphite has a diamagnetic susceptibility many times greater than that of carbon in other forms, either by itself or in combination. In the hope of elucidating this phenomenon, we were led to make a careful study of the X-ray diffraction patterns of purified graphite, using a narrow pencil of the K radiation of copper, and taking special pains to avoid fogging of the plate in the vicinity of the primary beam, either by stray radiation or by photographic halation. The diffraction photographs obtained with powdered graphite in this way show a new and hitherto overlooked phenomenon (Fig. 1). We find a notable amount of scattered radiation in the area surrounding the primary beam, terminating sharply at the first diffraction ring, and reappearing with a much smaller though quite sensible intensity in the area between the first and second diffraction rings.

These observations contradict the general belief that crystals or coarsely crystalline powders do not show any appreciable X-ray scattering at small angles with the primary beam (Hewlett, *Physical Review*, **20**, 688; 1922). Our experiments show the effect to become distinctly more noticeable when graphites of

increasing degrees of fineness obtained by sedimentation were used. Blank exposures taken without the graphite, and powder patterns taken with other organic crystals (for example, hexamethylene tetramine), do not exhibit the phenomenon; it cannot therefore be ascribed to the presence of white radiation or to stray X-rays. The peculiar distribution of the scattering, and especially its relation to the position of the diffraction rings, appear to us definitely to exclude the possibility of the effect being due to any admixture of adsorbed impurities or of amorphous carbon with the graphite.

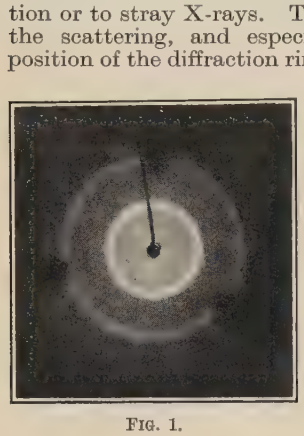

FIG. 1.

We are inclined to attribute the effects noticed by us to the fact that more or less loosely associated with the crystal lattice of graphite there are also certain mobile electrons which endow the substance with its high electrical conductivity. The success of Pauli, Sommerfeld, and others in developing the electron theory of paramagnetism and of metallic conduction on the basis of the Fermi-Dirac statistics suggests that even though graphite is strongly diamagnetic, certain electrons in it must possess large velocities, and hence cannot be regarded as an integral part of the lattice in respect of X-ray diffraction. They would therefore necessarily give rise to a scattering at small angles with the primary beam. The influence of particle size presumably depends on the magnitude of the free path of the electrons. We may interpret the increased intensity of the scattering with the finer powders as due to the distribution of the conduction electrons in the crystals becoming more and more completely chaotic with diminishing particle size. Such an interpretation is at least rendered plausible by the fact, discovered in a subsidiary investigation by Raman and Vaidyanathan, that the diamagnetic susceptibility of graphite is markedly a function of particle size, diminishing steadily to a small fraction of its full value with increasing subdivision of the substance.

Progressive Lightning.

ON Nov. 20, 1926, NATURE published an article by me with the above title, in which I described an instrument which I had constructed in the year 1900, for investigating the progress of a lightning flash; and in the issue of Sept. 1 of last year I gave an account of the first successful photograph with it. This I obtained at the Loomis Laboratory in August last. In this later publication I indicated an improved form of instrument in which two films are carried past two fixed lenses at the same speed in opposite directions, so as to give rise to opposite aberrations of the two images of the flash. From the distortions of the images so found, the rate and mode of progress of the flash could be determined.

Since September of last year I have very greatly improved and simplified the design of the apparatus, and I am proceeding now to make the patterns for the necessary castings. I shall be getting four sets of castings and eight objectives, reflecting prisms and ball bearings, so that I may have one set for myself, one for Dr. Simpson, and one each for Mr. Loomis and Prof. R. W. Wood, in the hope that the two last named will have a better chance of securing a successful result in the frequent summer storms in America. My object in asking NATURE to publish now a description of the proposed new instrument is to attract the interest of other experimentalists, for the provision of extra castings and other gear is more advantageously made all at once than piecemeal, and the working up of the parts to the finished instrument is a small matter. I may say that I have heard from Prof. Adolf Matthias, of Charlottenburg, that he is going to make up an instrument rather larger than the one which I am making, which he hopes to take to a good district for lightning this year. For this purpose I have already given him, for his own use, a description of the latest design. I am glad to find that he is of my opinion that results obtained by this method are unassailable.

The chief objection to the instrument proposed in NATURE of September last is the use of pairs of films. These are replaced in the present design by a single film, and by the aid of right-angled reflecting prisms set so as to turn the beam of light through a right angle the two images are formed on the same film.

The accompanying diagram (Fig. 1) is sufficient to illustrate the design. *D* is an aluminium drum turned

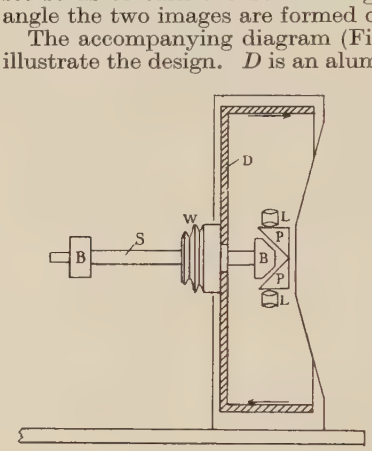

FIG. 1.

inside and out mounted on a shaft *S*, with pulley wheel *W* and carried on ball bearings *B B*. The drum may be driven by multiplying gear by hand or by motor directly coupled if preferred.

The shaft is directed towards the place where lightning ↑ is expected. The reflecting prisms *P P* and objectives *L L* form reversed images ← → on a film within the drum, and so the motion of the film gives rise to opposite aberrations. I have to thank Prof. Conradi, with whom I discussed the design last winter, for the suggestion to put the optical works within the drum instead of outside, as I was preparing to do. This has both optical and mechanical advantages. I am making the instrument to take standard Kodak films 30 in. × $2\frac{3}{4}$ in., which can be got anywhere. A drum such as this can easily be made to carry the film past the fixed images many times as fast as I carried the images over the fixed plate in my first apparatus. The film should, of course, be shielded from diffused light except at the places where the images will be formed. It would then be possible to run the drum until such a number as eight or ten flashes have been seen to be caught by the aid of a viewing prism, and no harm should result from general fog. I found with my revolving lens system that several bright flashes might supervene with none caught on the plate without serious fog, and the plate was not so shielded.

With such a camera as I have indicated above, re is good reason to expect that it would be possible detect the crawling of the lightning from point to nt in its length, for, in the much less powerful in- ument which I used in America, the two images of ash were clearly different in shape, indicating the gression of the flash.

t is evident that the optical parts could be carried an overhung shaft and be rotated within a fixed m, or by the aid of concentric shafts both optical ts and drum could be made to rotate in opposite ctions to obtain increased aberration if desired. I prefer the simpler plan described in the first ance. C. V. BOYS.

Striations in High Frequency Discharges.

N the course of an investigation dealing with the gin of the electrodeless discharge, high frequency ations have been observed in iodine vapour which apparently unlike those recently described either McCallum and Perry (NATURE, Jan. 12, p. 48) or herjee and Chatterji (NATURE, April 20, p. 605). m the accompanying photographs it will be seen

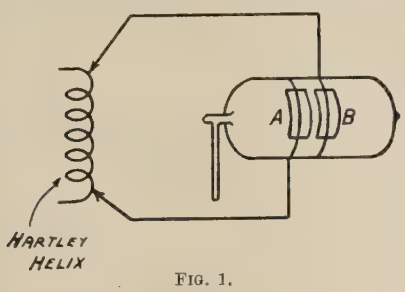

FIG. 1.

t the appearance of the striations is strongly gestive of a sine curve. They were first obtained dentally when a solenoidal coil was used with half wound back on itself, so that a high potential ted between the adjacent initial and final turns. the narrow region between these turns, of width ut one centimetre, the striation pattern was erved when the coil carried an undamped high uency current. It was afterwards found that, by ns of the arrangement shown in Fig. 1, conditions

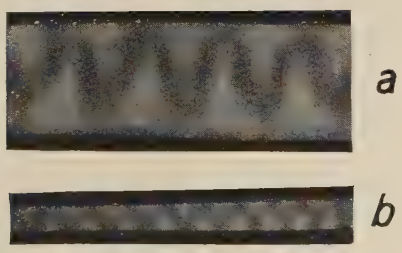

FIG. 2.

ld be controlled so as to permit of a more careful, vell as a photographic, study.

o keep the striations steady and well-defined, a able distance between the electrodes is necessary. quently, the whole pattern has a rotational motion, direction of which may be reversed sometimes ply by bringing the hand near the tube.

he length of the striations varies markedly with wave-length. Thus, photograph *b* (Fig. 2) was en with a wave-length of 65 m., and electrodes 3, 0·2 cm. apart; photograph *a* (Fig. 2), enlarged to the same extent, with a wave-length of 175 m., and electrodes 1 cm. apart. With a wave-length of 33 mm., the pattern was too fine to be photographed.

Although the striations resemble so strongly a continuous sine curve, a careful examination shows that they are in reality more like two sets of interlocking teeth. It is hoped that the exact origin of these striations will be revealed by the more extended investigation now in progress.

Dragonflies in Folk-Lore.

IN a recent letter to NATURE (June 1, p. 837) Dr. R. J. Tillyard directs attention to a chapter on dragonflies in the late Mary Webb's novel "Precious Bane". He asks if the expressions "ether's mon" or "ether's nild" used in that chapter for the dragonfly are still in use in Great Britain.

The novel is set, according to the introduction, in north Shropshire—the Ellesmere district. Hence it is worthy of note, I think, that here over the border in North Wales the Welsh name for the dragonfly, which is in common use throughout the province, is 'gwas-y-neidr'—the adder's servant. The choice of the word 'gwas' (servant) appears to be particularly suited to the legend given in "Precious Bane" which reads "where the adder lay hid in the grass there above hovered the ether's mon as a warning". An interesting parallel of the use of 'gwas' in natural history is found in 'gwas-y-gog', the cuckoo's servant, which name is given to the hedge-sparrow owing to the belief that this bird follows the cuckoo and permits the latter to lay its egg in her nest.

I am indebted to Prof. Ifor Williams (of this College) for looking up the Welsh names for the dragonfly in the older dictionaries. He informs me that Pughe, 1832 (2nd ed.), gives 'gwas-y-neidr' and 'gwaell neidr' as terms used for the dragonfly. The latter literally means 'the adder's knitting needle'. I am not aware of the use of this term in North Wales at present, but it is interesting to note that Dr. Tillyard states he believes the dragonflies are still commonly called 'devil's darning-needles' in many parts of the United States of America.

W. MALDWYN DAVIES.

Department of Agricultural Zoology,
University College of North Wales,
Bangor.

NEW ENGLAND is a long way from England, but our use of "darning needle", when I was a boy (Westborough, Mass., about 1895), is about the same as Dr. Tillyard's (NATURE, June 1, p. 837).

The 'darning needles', 'devil's darning needles', or 'blue darners' were definitely the smaller Zygoptera (Agrions). The 'blue darners' were of course in general the males, but we were not very careful in our distinctions. Larger dragonflies (Anisoptera) had no special name—they had to go as darning needles, but we felt the name did not really belong to them.

I have noticed that friends from the middle west, if they say 'darning needle' at all, mean especially the large Anisoptera; but they are more apt to say 'snake feeders', a term that is entirely unknown in our section, but recalls the "ether's mon" of Dr. Tillyard's letter. There is of course no real adder over here, and the word 'adder' is always used of a harmless snake.

I wonder if the difference of usage is related to the different source of the first immigration in the two parts of the country. New England was peopled from England and by Puritans—my own town was incorporated in 1717, long before the Presbyterian and Methodist immigrations, and still has a large proportion of the old stock. But the middle west had a substratum of Scotch, Scotch-Irish, and other Methodists and Presbyterians, dominating the New England overflow of Puritan stock. No doubt they brought different words, from a different part of Britain.

The Electromotive Behaviour of Single Zinc Crystals.

TO NATURE of Jan. 12, 1929, p. 49, Paul A. Anderson communicated some measurements of his on the potentials of single crystals of zinc. The investigation of a possible change of the electrochemical potential with the changing density of zinc atoms on different planes of the crystal was also the aim of an experimental research commenced in October 1928 in the Physicochemical Laboratory of the University of Latvia, in Riga, and is now in progress. The results obtained here do not agree with those of Anderson in so far as no difference could be found in the potentials of different, artificially prepared planes of single crystals of zinc against a neutral zinc sulphate solution. It must be admitted, however, that pyramidal faces were not investigated.

Each experiment consisted of four measurements on four planes ((0001), $(10\bar{1}0)$, $(11\bar{2}0)$ and polycrystal), which had undergone exactly the same previous treatment. The four electrodes were submerged to the same depth in the same vessel and measured against a calomel electrode.

In all cases the potential varied with (*a*) composition of the electrolyte: saturation with hydrogen increased the potential towards the less noble potentials as compared with oxygen saturation, addition of minute traces of acid greatly decreased the potential; (*b*) previous treatment: mechanical hard treatment, etching with very dilute and dilute acids, anodic treatment. But at the same time the four different planes showed no systematic difference in potential between themselves. This seems to be due to the following reasons:

1. Mechanical treatment (rubbing with emery, polishing, filing) disintegrates the ideal crystallographic planes. The resulting structure is indefinite and shows no differences of potential.

2. Etching with dilute acids after mechanical treatment attacks the surface very unevenly and no definite plane results.

3. The plane of etching does not develop parallel to the original plane when the surface of the crystal is etched anodically or with more concentrated acids strongly enough to show the structure of the crystal. This is particularly marked for the pyramidal faces investigated by Anderson and is not true for the basis plane. The consequence will be that several crystallographic faces will be present and the potential of the least noble face will be obtained.

The same equality of potential on the three different crystallographic planes was obtained for single crystals of zinc-cadmium (up to 0·2 per cent cadmium) alloys in neutral solutions (cf. *Zeitschr. für anorg. und allgem. Chemie*, **180**, 1; 1929).

Preservation of Animal Remains.

IN a belated copy of NATURE, dated Jan. 12, which reached me a short while ago, I read with much interest a review of a recent work written by Prof. Weigelt. In that review, entitled the "Preservation of Animal Remains", Prof. Watson enumerates modes of death which are "likely to affect large numbers of individuals at the same time". To those given the following may perhaps be added.

Geological work on the eastern edge of the Ufipa Highlands, south-east of Lake Tanganyika and a few miles from the western fault line of the Rukwa Trough or Rift Valley, has brought me into conversation with others who have an intimate acquaintance with this country. A member of the Brotherhood of White Fathers, Père Pourvoyeur, recently informed me of the effect of a strong wind from the south-east on Lake Rukwa. As may be seen on any good map, the lake is topographically prolonged in a northerly direction as a very flat plain, obviously a continuation of the area now covered by water, and recently part of the lake bottom. As an eye-witness, Père Pourvoyeur described how a strong wind from the south-east forced the waters of the existing lake over the flats, carrying both fish ('Siluridés') and crocodiles with it. The cessation of this wind and the consequent retreat of the water left very large numbers of fish and reptiles to die.

From the geological point of view, a difficulty is the sufficiently rapid entombment of the bodies before total decomposition had destroyed everything, a difficulty seemingly equally applicable to the instance of Smithers Lake quoted by Prof. Watson. During some geological periods, the rate of sedimentation may have been much more rapid than any known at the present time, except in peculiar circumstances as an abnormality. At Kindope, north of Tendaguru Hill, the skeletons of a herd of reptiles were unearthed in a relatively small space by the German expedition which first worked that celebrated locality in Tanganyika Territory for Deinosaur remains. The enclosing silts are frequently false-bedded on a very small scale; the planes of lamination change direction three or four times in a few inches, suggesting the swirling action of a slowly moving quicksand. At Tendaguru also the occurrence of large isolated bones surrounded by fine-grained sands and silts implies, during the time of deposition, that the sediments had a consistency approaching that of cream. These would constitute cases where large numbers of individuals "have an exceptionally favourable chance of being preserved".

Kinematographic Record of Sunrise on the Moon.

ON the night of May 17–18, 1929, between 1·5 h. and about 5·5 h. Greenwich civil time (18 d.) a moving picture was made here of the lunar crater Copernicus, showing changes in the shadows at sunrise. A Victor kinema camera, using amateur-size film (16 mm.), was employed, attached in the focal plane of the 23-inch refractor (30 feet focal length) of the Princeton University Observatory. A yellow Wratten filter No. 45 was inserted about 15 inches ahead of the film. Exposures were made every 6 seconds, approximately, for about 4 hours, on Agfa negative film. The duration of each exposure was about 3·8 seconds, controlled by the rotating camera shutter (sector opening 200°), which was driven by a belt from a light electric motor carried in the same aluminium frame.

More than 50 feet of film was obtained, with above 00 successive pictures of a region around Copernicus, out 200 by 330 miles in size, the ring-plain being in middle. Guiding was with a power of 700 and a cial eyepiece, which received light from a cube sm just ahead of the film, the diagonal surface of ich was lightly silvered to divert about half of the ht.

The exposure was too short to show the faint mination on the low-lying areas outside Copernicus the exact terminator; but the retreat of the shadow the 'eastern' ridge down the inner slope of the estern' ridge is well depicted. The age of the moon s 9·0 d. on May 18 at 6 h. G.C.T. The guiding was ly fair, but the positive made from the film makes good show when projected. (It will be remembered at Jupiter has already been depicted in motion tures by W. H. Wright.)

Further development of the apparatus is planned. e low illumination at the terminator offers the chief ficulty, because if the exposure is made long, the ole film is rather short when projected. Technically isfactory pictures may be helpful to serious investi- tors of the detailed topography; but the vivid neral interest possessed by moving pictures of the on justifies the effort of securing them.

Heisenberg's Indetermination Principle and the Quantum.

THE Heisenberg principle states that $\delta p \delta q \sim h$, where and q are two canonical conjugates. Energy and ne are such conjugates. For the quantum, $E = h\nu$ d we have

$$\delta(h\nu)\delta t \sim h \text{ or } \delta\nu\delta t \sim 1 \quad . \quad . \quad (1)$$

ere t is the time the quantum has been travelling m its source. If x is the distance the quantum has velled in time t, then $\delta t = \delta x/c$, where c is the locity of light, so that

$$\delta\nu\delta x \sim c \text{ or } \delta\lambda\delta x \sim \lambda^2 \quad . \quad . \quad (2)$$

ce $\delta\nu = c\delta\lambda/\lambda^2$, neglecting sign.

From the classical theory (Compton, "X-Rays and ectrons", p. 55) the amplitude of a radiating illator decreases according to $A = A_0\epsilon^{-kt}$ due to mping, where $k = (4\pi^2/3) \cdot (e^2/mc\lambda^2)$ and e is the arge on the electron. The effective length of a ve-train may be taken as the length for A to be duced to A_0/ϵ and is c/k. This length may be taken the uncertainty δx of the position of the quantum, that

$$\delta\lambda \sim k\lambda^2/c \text{ or } \delta\lambda \sim (4\pi^2/3) \cdot (e^2/mc^2). \quad . \quad (3)$$

I have previously calculated the width of a spectrum e due to damping by the method of the Fourier egral (*Phys. Rev.*, **19**, 64; 1922) and have obtained width $\Delta\lambda$ between half values of the maximum ensity of

$$\Delta\lambda = (4\pi/3) \cdot (e^2/mc^2) \quad . \quad . \quad (4)$$

It is interesting to note that $\delta\lambda$ and $\Delta\lambda$ are of the me order, namely, 10^{-12} cm. Does the Heisenberg inciple therefore imply that a spectrum line given t by, say, a mercury atom, has a width in addition the width due to the Doppler and pressure effects? n a single quantum itself have a frequency width? hen mercury resonance radiation is absorbed in rcury vapour, it seems necessary to assume a dth for a single quantum if any absorption at all to occur.

G. E. M. JAUNCEY.

St. Louis, Mo., U.S.A., May 24.

Vibrational Quantum Analysis of Red Cyanogen Bands.

A STUDY of the red cyanogen bands shows that the band at $\nu 14430$ is not the true $0\text{-}0$ band of the system. Six new bands on the higher λ side have been photographed on neocyanine plates, from the spectrum of cyanogen as developed in active nitrogen (R.K.A.) and of the high current density arc (J.W.R.). These can be fitted in a simple manner in the existing n'/n'' table for the red cyanogen bands, by extending the n' progressions as under:

n'/n''.	0.	1.	2.	3.	4.
0	10937 (*a*)				
1	12697 (*a*)	10654 (*b*)			
2	14432	12393 (*a*)			
3	16143	14099	12086 (*a*)		
4		15788	13769	11782 (*a*)	
5			15430	13439	11480 (*a*)

Numbers denote ν of the most refrangible head.
(*a*) denotes *new* bands found in active nitrogen and in arc.
(*b*) found in arc only.

This arrangement does not invalidate the existing analysis completely, and appears to be satisfactory. It is not certain that the band at $\nu 10937$ is the $0-0$ band, which may be higher up in the infra-red, beyond the range of sensitivity of the photographic plates now available. ω_0'' and $\omega_0''x''$ retain their old values; ω_0' is uncertain, but $\omega_0'x'$ retains the old value. The vibrational equation deduced from the present experiments, assuming $\nu 10937$ to be the $0-0$ band, is:

$$\nu_{(\text{head})} = 10937 + (1782\,n' - 13{\cdot}5\,n'^2) - (2055\,n'' - 13{\cdot}3n''^2).$$

The Raman Effect in Carbon Disulphide.

IN view of the interesting observations of Rasetti with carbon dioxide (NATURE, Feb. 9 1929), the Raman spectrum of which was found to contain no lines corresponding to any of the observed infra-red absorption bands, the results obtained in the analogous compound carbon disulphide may be noteworthy. The scattered spectrum of this liquid gives two prominent frequency shifts, 655 and 800, corresponding to $15{\cdot}27\,\mu$ and $12{\cdot}50\,\mu$ respectively. The infra-red absorption of the liquid was studied by Coblentz in the region $2\,\mu$ to $15\,\mu$, and he gives the following values for the absorption bands—$3{\cdot}2\,\mu$, $4{\cdot}6\,\mu$, $6{\cdot}8\,\mu$, $11{\cdot}65\,\mu$, and $13{\cdot}4\,\mu$. All these bands, except the first, are very strong, the one at $6{\cdot}8\,\mu$ being the most prominent. It is significant that none of these bands are represented in the scattered spectrum.

The Raman line corresponding to the frequency shift 655, excited by 4358, is very strong in the spectrum and has an anti-Stokes' line the intensity of which is less than 1/50 of it. The value calculated for the intensity ratio between the negative and the positive lines according to the relation $e^{-h\nu/kT}$ comes out to be 1/20. Whether this discrepancy in the relative intensity has any connexion with the absence of the corresponding infra-red absorption remains to be determined.

The Ozone in the Earth's Atmosphere.

By Dr. D. N. HARRISON.

THE first accurate measurements of the amount of ozone in the atmosphere were made by Fabry and Buisson at Marseilles in 1920, and their method has been modified and developed by Dr. G. M. B. Dobson and others,[1] so that ozone observations are now made regularly at least once a day at about half a dozen places in different parts of the world. The results obtained up to the present from these series of observations are the subject of this article.

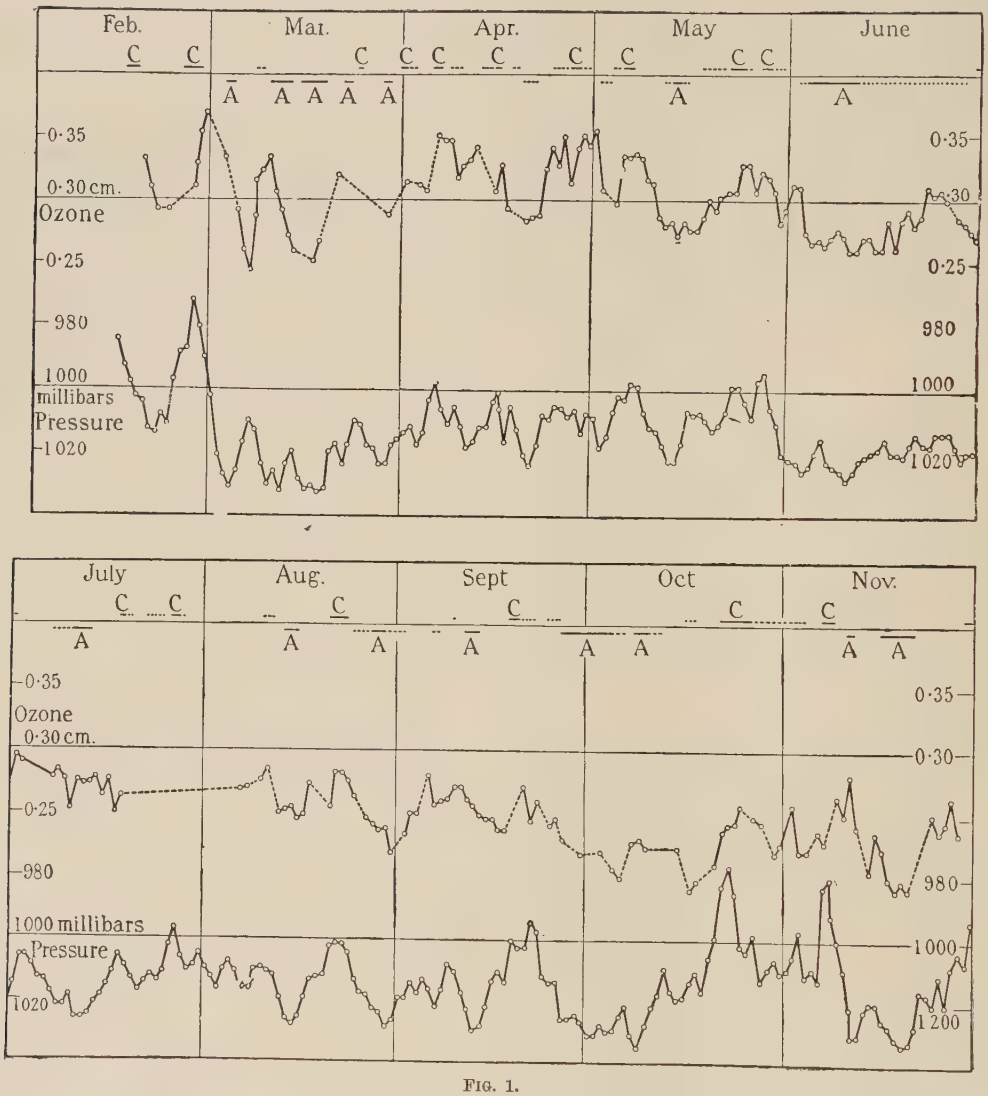

FIG. 1.

Ozone has an absorption spectrum consisting of bands in the infra-red, a weak band in the visible, and a very strong band in the ultra-violet, which cuts off the solar spectrum completely at about 2900 A. Its equilibrium temperature in sunlight is therefore higher than that of the other constituents of the atmosphere, which have no ultra-violet absorption. Moreover, atmospheric ozone was known to be confined to a region many kilometres above the earth's surface. Thus variations in the amount of ozone would be expected to affect the temperature of the upper atmosphere, and it was thought that in this way it might play an important part in the various changes which the atmosphere undergoes.

Ozone, as is well known, is a form of oxygen having three atoms in the molecule. It is formed from oxygen by the action of ultra-violet light of shorter wave-length than that which ozone itself absorbs. The spontaneous decomposition in the absence of a catalyst is extremely slow, but by absorbing ultra-violet radiation ozone is transformed into oxygen, so that in the absence of other factors the amounts of oxygen and ozone would

[1] *Proc. Roy. Soc.*, A, vol. 110 (1926), p. 660; vol. 114 (1927), p. 521; vol. 122 (1929), p. 456.

tend toward equilibrium, depending on the distribution of intensity in the solar spectrum. It was thought at one time that solar radiation was one of the main sources of atmospheric ozone, but this is probably not the case, for reasons which will be explained later.

METHOD OF MEASUREMENT.

Briefly, and without technical details, the method by which ozone is measured is as follows. The method is spectroscopic; since ozone absorbs ultra-violet light of certain wave-lengths, the intensity of this light reaching the earth from the sun depends on the amount of ozone in the atmosphere; the intensity of the light is measured photographically, and consequently the amount of ozone through which it has travelled can be found. This is expressed as the thickness of a layer of the pure gas at N.T.P.; it varies about a mean value of roughly 3 mm. in Europe. In actual fact, of course, the ozone is spread through an unknown depth of the atmosphere, and this method of expression merely gives the number of molecules per horizontal square centimetre. The accuracy of the measurements is such that the results can usefully be expressed to three significant figures; the unit is usually taken as 0·001 cm., so that 321 would mean that the amount of ozone was equal to that in a layer 0·321 cm. thick at N.T.P.

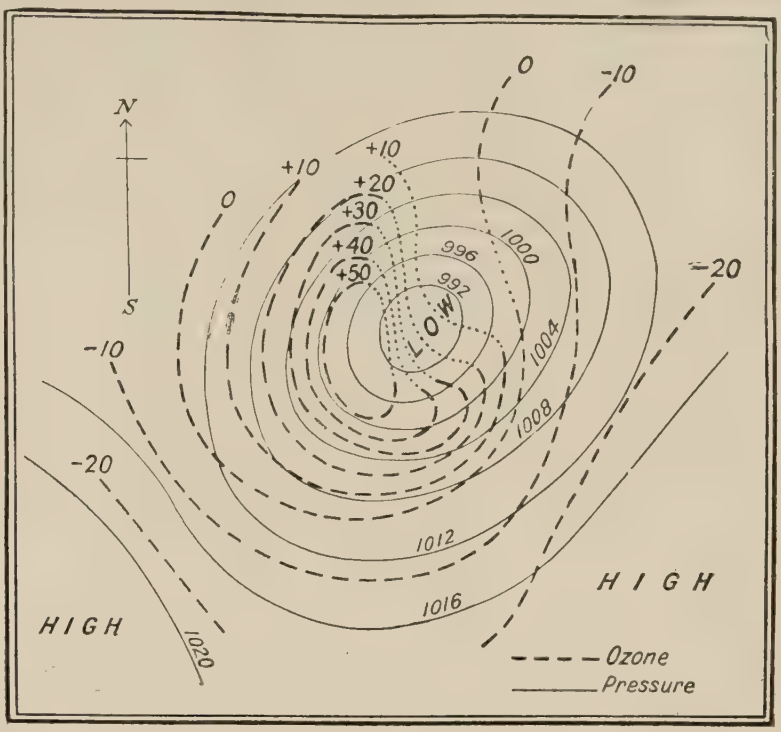

FIG. 2.

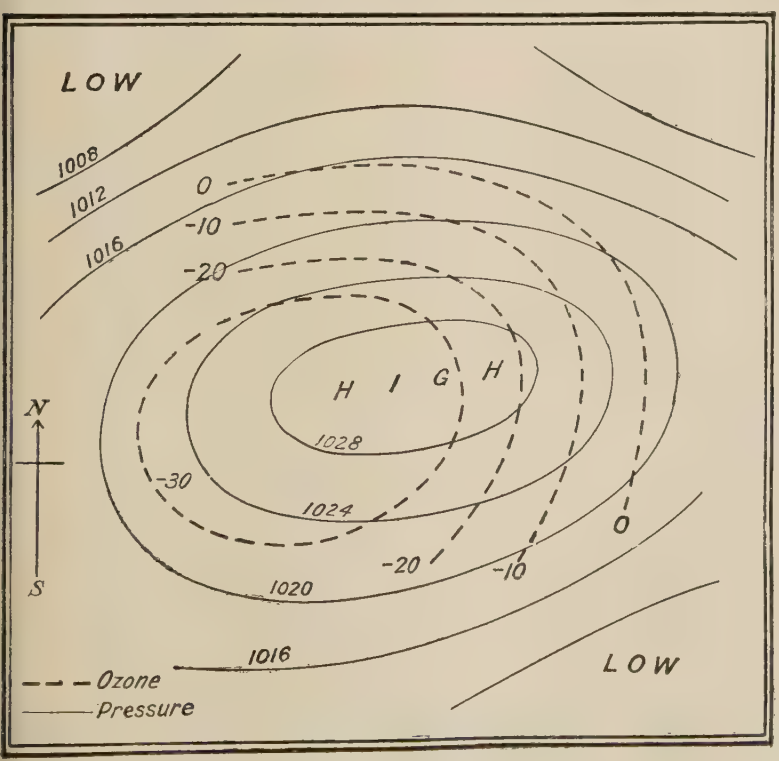

FIG. 3.

The height of the ozone layer can also be deduced. Several different workers agree in placing it at about 40-50 km.; this probably represents the 'centre of gravity' of the layer. The height appears to be greater when the amount of ozone is large than when it is small.

DIURNAL AND ANNUAL VARIATIONS.

It was discovered at Oxford in 1925: (1) that the amount of ozone can vary greatly from day to day, and indeed during one day; (2) that these variations have an inverse connexion with the barometric pressure; and (3) that there is a marked annual variation with a maximum of about 330 in April and a minimum of about 220 in October, taking a smooth curve through the year. Fig. 1[2] shows the ozone values for 1925, together with mean

[2] The illustrations are reproduced by kind permission from the *Proceedings of the Royal Society*.

pressure for each day at Oxford. The short horizontal lines A and C above the curves mark the occurrence of cyclones and anticyclones.

are accompanied by definite and characteristic changes in the quantity of ozone in the atmosphere above any given place. Measurements

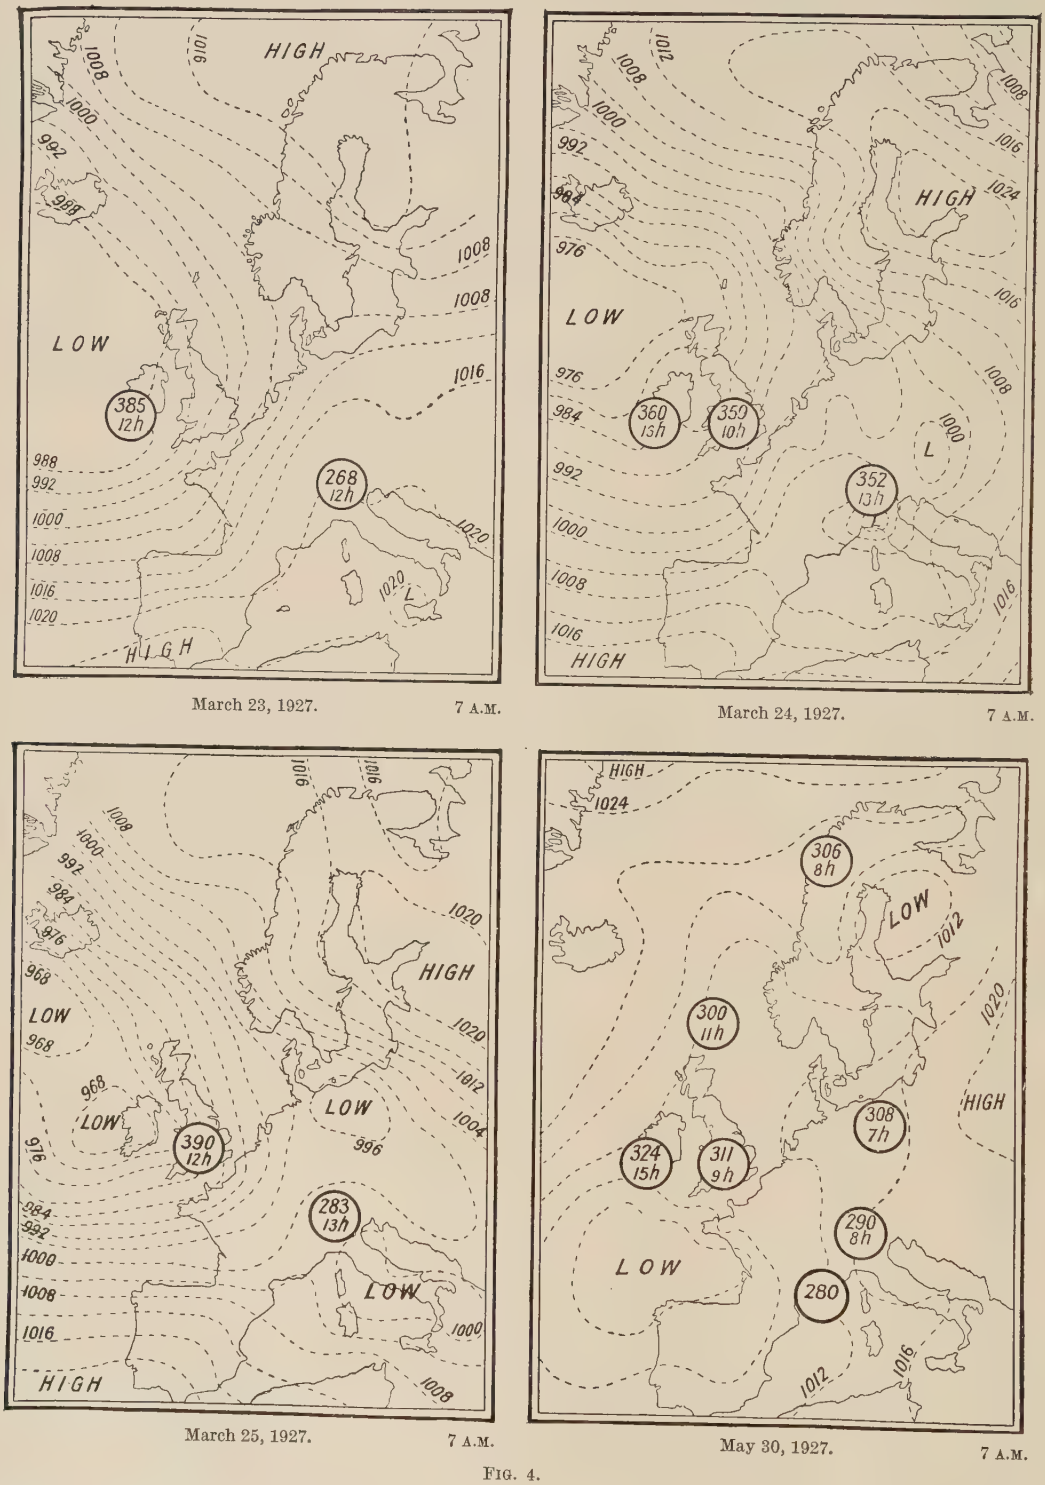

FIG. 4.

Subsequent observations at other places confirmed and amplified these conclusions, and it is now certain that the various sequences of weather were made at Oxford, Lerwick (Shetland), Valentia (south-west Ireland), Abisko (Norway), Lindenberg (near Berlin), Arosa (in the Alps), and Marseilles

during 1926 and 1927, with the view of discovering the distribution of ozone at different times, in the same sort of way as that in which weather maps are plotted by the aid of a network of reporting stations.

OZONE AND WEATHER.

The general conclusion so far reached is that there is a very close connexion between the ozone and the origin of the great air-currents the interplay of which gives us our 'weather'; the connexion is closest when the air considered is that not at the surface, but in the stratosphere (the isothermal region) which begins at a height of roughly 10 km. These currents are named by meteorologists 'polar' and 'tropical'; polar air is associated with high ozone values and tropical air with low ozone values. When studied in connexion with a weather map, the changes of ozone with the fluctuations of these air masses are most striking. There are difficulties, however, in the way of assuming that the varying quantities of ozone are actually brought by the air-currents.

Fig. 2 shows the average distribution of ozone in a cyclone. It was obtained by drawing the isobars for a typical or idealised cyclone, and plotting for each individual case the ozone value in its appropriate position; in order to eliminate the annual variation, the ozone values are expressed as differences from the mean for the time of year, so that the figure shows in units of 0·001 cm. the changes which, on the average, take place during the passage of a cyclone. (The figure should be imagined to move from left to right, that is, from west to east.) It will be seen that the ozone begins to fall at some distance in front of the depression, when tropical air is arriving at high altitudes, remains low during the passage of the 'warm sector' (roughly the south-east quadrant of the cyclone), and rises rapidly just behind the centre; this sequence of changes in a cyclone is found practically without exception, and even a small secondary (judged from the weather-map) may be followed by a large and abrupt rise of ozone. The highest ozone values found are those at the rear of depressions.

Fig. 3 shows the average distribution of ozone in an anticyclone; here we see that ozone tends to be low and that the minimum comes after the maximum of pressure.

The highest value hitherto found is 420 and the lowest 172.

Typical 7 A.M. weather maps, with ozone-values and hours of observation, are reproduced in Fig. 4. In the first three maps the passage of a secondary depression over Arosa is accompanied by a large but temporary rise of ozone; in the fourth map comparatively uniform conditions are illustrated.

The correlation co-efficients between the amount of ozone and upper air conditions are among the highest found in meteorology. The correlation with surface pressure is high, but those with the pressure at heights of 9-14 km. are much higher, and very high values are found for temperature in the troposphere and for the height of the base of the stratosphere; these are all negative, as would be expected from what has been said, while that for the temperature at 14 km. (in the stratosphere) is positive.

So far we have considered the distribution in Europe, about the latitude of Great Britain. We now turn to the world-wide distribution, so far as it is known. Observations at Montezuma (Chile) and at other places within the tropics give remarkably uniform and constant values of about 200 to 220, which is about the value found for tropical air in Europe in the summer. At Montezuma there seems to be a small annual variation, with a maximum in the southern spring.

Observations in high latitudes are scanty, but it seems probable from the Abisko figures that there is a maximum of perhaps 400 in the spring, after which the amount of ozone falls rapidly through the summer and autumn. In this connexion Prof. Rosseland's letter in NATURE, Feb. 9, is of interest. As was predicted by Dr. Dobson, photographs of the spectra of stars taken within the Arctic circle in December were cut off at 3000 A. by ozone.

A few observations from New Zealand indicate that there the amount and variations of ozone are similar to those in Europe.

ORIGIN OF OZONE IN THE ATMOSPHERE.

These results are of great interest from their bearing on the probable origin of atmospheric ozone. The ozone is at a minimum in the tropics; it is at a maximum in Arctic regions after the winter night, and decreases rapidly as the sunlight becomes stronger. Therefore we must conclude that the amount of ozone in equilibrium in sunlight is relatively small (perhaps about 2 mm.) and there must be some other source of supply. The rate of decomposition in sunlight must be slow, since observations near sunrise and sunset indicate no regular decrease during the day.

The origin may possibly be found in the aurora, or some associated phenomenon of which we know nothing. The amount of ozone is related to magnetic conditions in the sense that high ozone values tend to occur at times of magnetic disturbance, and a marked auroral display is always accompanied by a magnetic storm. Nevertheless, the aurora is situated at a height of 100-500 km., far above that found for the ozone layer. Further evidence of the presence of ozone at about 50 km. is given by temperatures found near this level. Dobson's and Lindemann's observations of meteors gave a high temperature above 55 km., and observations of sound-waves indicate a temperature at about 40 km. as high as that at the earth's surface.

Although no simple relation between ozone and weather has been found, the results here outlined show that the problem is full of interest; and in any case no one would expect, with such a complicated machine as the earth, its atmosphere, and the sun together form, to disentangle one complete thread of cause and effect.

Polyploids and Polyploidy.

By C. D. DARLINGTON.

WHEN a cell divides to produce two daughter cells having the same genetical properties as itself, the nucleus resolves itself into a definite number of structures, the chromosomes. These, splitting lengthwise, give rise to two identical groups which go to make the daughter nuclei. In this process, known as mitosis, it is evident that, with certain exceptions which need not be gone into here, the chromosomes into which the nucleus resolves itself are always identical in number and form with those which went to constitute it at the preceding division. The chromosome number is said to be constant. It follows that when, in the course of sexual reproduction, two germ-cells unite to form a zygote and their nuclei fuse, the new generation of cells thus established will show at mitosis a new chromosome outfit or 'complement', the sum of those of the two germ-cells. When these are identical the number will be simply doubled, and in these circumstances the number of chromosomes in the germ-cell is said to be 'haploid' and the double number of the zygote is said to be 'diploid' (see Fig. 1). Further, when the

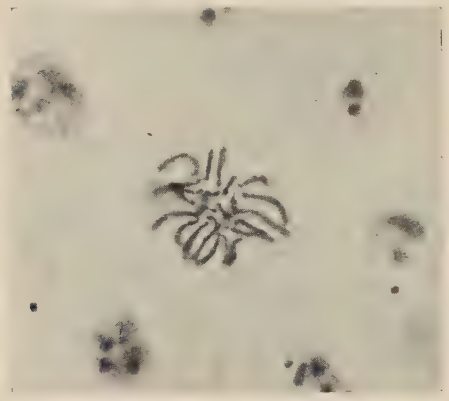

FIG. 1.—The diploid chromosome number (24) in a root tip of *Tulipa Clusiana*, a form from Tibet.

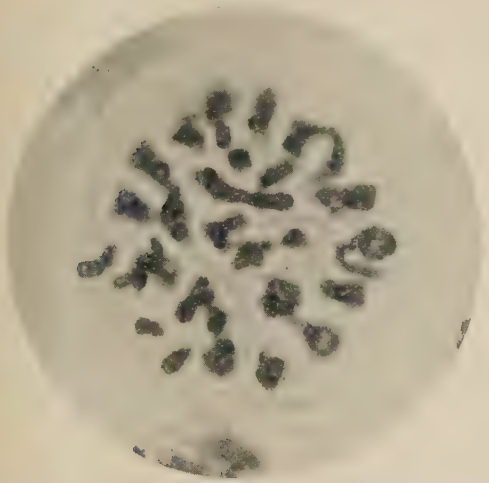
new zygote comes to produce germ cells, which by their union will reconstitute a diploid individual like itself, the zygote nuclei undergo a process of 'reduction', by which a new cell generation is produced having the haploid number of the gametes.

These three processes provide the mechanism that determines the Mendelian laws of inheritance, and so long as mitosis, fertilisation, and reduction follow a regular course, the Mendelian laws, with all the complications that are implicit in them, are obeyed. But all three processes are liable to error. In the first place, we frequently find body cells, both in plants and animals, the chromosome numbers of which are double those characteristic of the individual and its species. This type of 'doubling' probably follows the failure of two bodies of chromosomes to separate after mitosis, or the simultaneous division of two nuclei which have not been separated by a cell-wall after the preceding cell-division. In plants, owing to their unlimited growth, such 'doubled' cells sometimes produce germinal tissue, and a new tetraploid race, such as *Primula kewensis*, with four times the haploid chromosome number, is established. Doubling is so frequent in the formation of a callus in the tomato that we can be certain of obtaining a proportion of tetraploids amongst the adventitious shoots thrown up from the callused wound when the stem is cut off. In the normal course of development, doubling has been found to occur frequently in the embryo-sac nuclei of several plants belonging to the Liliaceæ. Usually the doubling occurs at the opposite end of the embryo sac from the egg-cell, but sometimes the egg-cell itself is affected, and in these cases fertilisation of the diploid female gamete will produce a new triploid individual.

In the second place, abnormalities in fertilisation occur which give rise to a different kind of change. Various stimuli may excite the development of the egg-cell without fertilisation. For example, when an interspecific cross, such as hexaploid *Solanum nigrum* by tetraploid *S. luteum*, is attempted, the stimulus of pollination sometimes excites the development of the egg-cell with the reduced (triploid) number, although the pollen-nucleus does not fuse with the egg-nucleus. Similarly, by the stimulus of changes of temperature, an egg-cell in *Datura* can be induced to develop. In these ways a haploid, or relatively haploid, individual arises having the hereditary material of a germ-cell and the outward form, on a reduced scale, of a diploid plant. Experimentally it has been found possible to induce the fusion of two male germ-cells with one female; in the formation of the endosperm we have virtually the reverse case of the fusion of two female germ-cells with one male. From both these unions a triploid cell generation is produced.

It is in the finely regulated processes of reduction, however, that irregularities most frequently occur, and these irregularities are of great importance in the production of polyploids. In considering reduction, two properties of the chromosomes should be particularly borne in mind. First, the material of which the chromosomes are made up has specific physiological properties, so that, to take a simple example, if one type of chromosome is represented in the organism three times instead of twice, constant physiological changes are produced. To take another example, if one of the chromosomes of a haploid gamete is lacking, the gamete is not usually viable. Secondly, where, as is usually the case, the diploid organism is the result of the union of two similar gametes, the chromosomes contributed by these gametes must correspond in pairs. They must be structurally and functionally homologous. When, therefore, we see pairs of chromosomes formed at reduction, it is a legitimate assumption that these are pairs of homologous

hromosomes and that they pair because they are ke. Further, where pairing fails, it is perhaps atural to conclude that this failure is the result f lack of likeness or affinity. Exceptions to this ıle we shall return to later. In the main it is true,



IG. 2.—Pollen mother-cell division in a pentaploid form of *Tulipa Clusiana* (60 chromosomes) showing associations of various numbers of chromosomes, and some chromosomes unpaired.

nd it is as a consequence largely of failure of airing that irregularities in reduction arise in ybrids.

The simplest form that these irregularities can ake is the failure of the two corresponding groups f chromosomes to separate, and the consequent rmation of a single nucleus with the diploid umber. This nucleus then divides to give two uclei in which the number is similarly unreduced. erm-cells have been shown to arise in this way in rge numbers of plants, which are either of known ybrid origin (like *Raphanus-Brassica*) or believed n independent grounds to be hybrids (like species f *Hieracium*). In *Pygæra* hybrids, where the rmation of diploid germ-cells, with complete ilure of chromosome-pairing, was first observed, ıe nuclear phenomenon was shown to be corre-ted with the fact that the character differences mpletely fail to segregate. This is one of the scoveries on which the chromosome theory is ased.

If the conditions of the origin of polyploids *before e fact* are almost universal, the conditions *after e fact* impose important limitations on their aintenance. These limitations are almost all ound up with the processes of sexual reproduction. here the sexes are differentiated, doubling of the romosome number may be associated with erility on one side, as in *Pygæra* hybrids, and nsequent failure of the tetraploid to perpetuate elf; or there may be a change in the method of production, as in *Artemia* where a tetraploid is rthenogenetic, or *Empetrum* where a tetraploid hermaphrodite, the diploid that probably rresponds being in each case unisexual.

In a different way the purely mechanical con-tions of reduction greatly limit the success of those polyploids which reproduce sexually. The conditions under which the corresponding chromosomes separate regularly when present in pairs are not always equally satisfactory when more than two of each kind are present. For example, in a triploid, where there are three of a sort, the odd chromosomes, whether associated with the pairs or not, separate at random to the two daughter cells. Consequently the germ-cells produced have chromosome numbers varying between the haploid and the diploid number (see Fig. 3). In these new intermediate types the balance of the physiologically differentiated chromosomes is new, untried, and in most cases unsuccessful. Most triploids are therefore sterile so far as sexual reproduction is concerned. Triploidy is none the less common both in natural species and in cultivated plants, but a study of its incidence shows that in these established triploid forms sexual reproduction has lost its value. Triploids occur, for example, in plants with various kinds of natural vegetative propagation in *Hyacinthus*, *Tulipa*, *Iris*, *Rubus* (Fig. 4), *Canna*, and *Tradescantia*; with reproduction by grafting in *Prunus*; with apogamy in *Hieracium*; with partial parthenocarpy in the cultivated apples; and probably with both apogamy and parthenocarpy in cultivated *Citrus*. To such forms as these it is clear that ordinary seed fertility, so far from being an advantage, may actually become a hindrance.

The case of tetraploids is more complicated, both in regard to chromosome behaviour and to the fertility that largely depends on it. For the sake of simplicity, let us take two opposite types. From a haploid *Datura*, itself the result of the development of an unfertilised egg, diploid offspring have

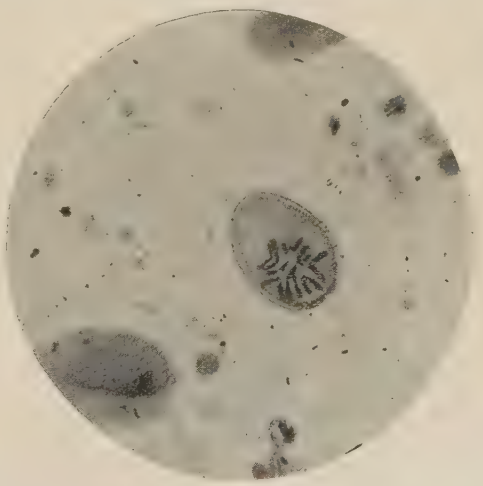


FIG. 3.—A pollen grain of a triploid hyacinth (somatic number, 24) showing 13 chromosomes; numbers between 8 and 16 have been found. Note the three chromosome types.

arisen by failure of reduction, and from these again tetraploids. In such tetraploids there are four identical representatives of each chromosome type, which usually associate to form quadrivalent bodies at reduction. These quadrivalents are, of course, capable of dividing into two and two, but seem to

be subject to irregularity in division, for gametes arise (as in tetraploid *Prunus cerasus* and *Tradescantia virginiana*) both with more and less than the normal gametic number, and the fertility of such tetraploids is consequently reduced.

We may mention parenthetically that, just as the functional gametes must contain two out of the four chromosomes of each type chosen at random, so the breeding results in tetraploid *Datura* and *Primula sinensis* have always agreed with the assumption that two Mendelian factors, chosen at random from four, pass to each gamete. This agreement, verifying prediction, is a substantial corroboration of the chromosome theory of heredity.

On the other hand, we have tetraploids arising as a result of doubling in hybrids. The result depends on what we may loosely call the 'degree of hybridity.' *Primula kewensis* is not an extreme example, and will serve to show the peculiarities

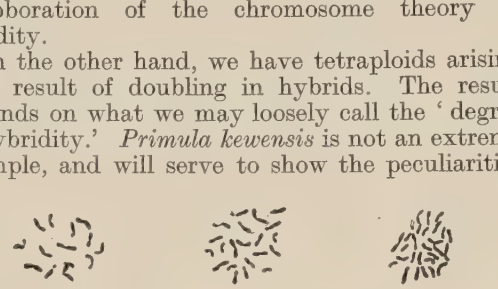

FIG. 4.—Diploid and polyploid species and varieties of *Rubus*. All the even multiples are fertile, although the tetraploid and hexaploid are known to be interspecific hybrids. The odd multiples are both sterile in a high degree.

associated with various degrees of hybridity. It is the result of a cross between *Primula floribunda* and by *P. verticillata*, which gave in the first instance a sterile intermediate diploid hybrid, as might have been expected. This diploid produced a giant fertile shoot the offspring of which were fairly constant, giant, and fertile like itself. This shoot was tetraploid and must have arisen as a result of the formation of tetraploid somatic cells, as in *Solanum*. In the diploid hybrid, the corresponding chromosomes of the two parental species paired at reduction; its sterility must therefore be assumed to be the result of failure of the new genetic combinations brought together in the gametes. In the tetraploid, however, pairs are usually formed as in the diploid, but the general absence of segregation means that identical mates must pair and pass to opposite gametes.

This conclusion is justified by the fact that a small proportion of segregates is produced bearing certain characters of the parental species, that is, no longer intermediate in every respect. In a similar small proportion of cases the chromosomes associate in fours, derived therefore from both species and capable of yielding gametes pure in the characters of one species carried by the chromosomes concerned. It follows that the constancy and relative fertility of the hybrid tetraploid depends on its degree of hybridity, for, in so far as the corresponding chromosomes of the opposite species are capable of pairing in the tetraploid derivative, dissimilar gametes will be produced, both as a result of genetic segregation and abnormality in the division of quadrivalents. In both cases fertility is reduced.

These remarks, which are based on theoretical considerations, are in agreement with all the available experimental evidence. Fertile diploids such as *Œnothera Lamarckiana*, *Datura Stramonium*, *Primula sinensis*, *Solanum Lycopersicum*, and *Campanula persicifolia* give less fertile tetraploids. Sterile diploids such as *Primula kewensis*, *Raphanus-Brassica*, and relatively diploid *Nicotiana* and *Solanum* hybrids give more fertile tetraploids.

It is therefore possible for a tetraploid arising from a hybrid diploid to have the mechanical properties of a fertile diploid. But it combines with these certain genetical peculiarities. Not only is it a hybrid, with such physiological advantages as hybridity may confer, but occasionally the corresponding chromosomes of the opposite diploid parents may pair. The tetraploid will then show the segregation of a hybrid, and may give rise to offspring with any workable combination of the characters of its two parents.

(*To be continued.*)

Obituary.

PROF. R. J. HARVEY-GIBSON.

THE death in Glasgow on June 3, at sixty-nine years of age, of Dr. Robert J. Harvey-Gibson, emeritus professor of botany in the University of Liverpool, will be widely regretted. Prof. Harvey-Gibson was a son of the manse and was educated in the Universities of Aberdeen, Edinburgh, and Strasbourg. He first held appointments as demonstrator in zoology and later in physiology in the University of Edinburgh. His association with the University of Liverpool goes back to the year 1883, in which his first appointment was that of demonstrator in biology in the old School of Medicine, which was later amalgamated with University College as the foundation of the present University. At the amalgamation, Harvey-Gibson was promoted to a lectureship in botany, which became in 1887 a subject in the new Faculty of Science. The institution and growth of a Department of Botany under his direction soon followed, and in 1889 a new laboratory was erected to meet the needs of the Department. The first assistant in the Department was Dr. A. J. Ewart, and when in 189[illegible] Mr. Holbrook Gaskell made possible the foundation of a chair of botany, Harvey-Gibson became its first holder and worked arduously for the advancement of the Department and the acquisition of modern laboratories. At that time Dr. J. C. Willis was a student in the Department. In 1900 Mr. Hartley offered to build a new laboratory, and in 1902 the present Department was erected to the plans o

rof. Harvey-Gibson, and was officially opened by ir W. Thiselton-Dyer.

It may truly be said that Harvey-Gibson de-oted himself to the construction and equipment of department, and that in this he built largely for is successors. Yet he found time for investiga-ion and writing on varied subjects, for he was of atholic interests, and for administration in many elds of University activity. His chief contribu-ons to his subject are a series of papers on marine lgæ, the Lycopods, and on questions of systematic natomy, and he was the author of philosophical ssays, an outline of the history of botany, and other orks of a more general nature. He was keenly nterested in the military training of undergraduates nd was the founder of the Officers' Training Corps f his University. During the War he served as a olonel in the Territorial Army and took an active art in the work of the Red Cross Society.

Harvey-Gibson was a man of scholarly achieve-ent, and although he had been in indifferent ealth for some years, he maintained a lively in-erest in all branches of his subject and in classical tudy.

Mrs. Theodore Bent.

THE death of Mrs. Theodore Bent on July 3, at he age of eighty-three years, has removed a strik-ng personality for many years familiar in literary nd scientific circles in London. She was the widow f Theodore Bent, whom she married in 1877. Of rish extraction, she preserved to the end of her fe some of the characteristics of her nationality, otably readiness in conversation and a sharpness n repartee.

Mrs. Bent accompanied her husband and gave im valuable assistance in his many journeys of archæological exploration. Their first important expedition was in the Aegean Islands in 1885–86 and 1886–87. In the latter year Bent was excavating in Thasos under the auspices of the Society for the Promotion of Hellenic Studies. Journeys to Asia Minor in 1888 and to the Bahrein Islands in the Persian Gulf in 1889 were followed by their best-known expedition in 1891, when they visited South Africa to study the ancient ruins at Zimbabwe in Mashonaland, then examined and measured systematically for the first time. The results of the expedition were embodied in "The Ruined Cities of Mashonaland" which appeared in 1892. Bent held the view that the builders of Zimbabwe were a northern race from Arabia, and for the rest of his life—he died in 1897—their expeditions had as their object to discover traces of such a race. They visited Abyssinia and the southern part of Arabia, of which they made a special study, visiting the almost unknown Hadramut country. Their last journey was through the Vafei and Fadhli countries in March 1897, Mrs. Bent giving an account of this journey to the Royal Geographical Society.

Mrs. Bent was an experienced photographer, as well as an accurate observer, as was shown by the book "Southern Arabia", published in 1900, which was written mainly by her with the aid of her husband's journals. One book which she wrote apart from her husband was "Anglo-Saxons from Palestine", published in 1900, in which she showed herself an adherent of the Anglo-Israelite theory.

WE regret to announce the following deaths:

Mr. A. B. Bruce, formerly of the Indian Civil Service and of the Ministry of Agriculture, on July 2.

Prof. L. T. Hobhouse, Martin White professor of sociology in the University of London, on June 21, aged sixty-four years.

News and Views.

AN honorary fellowship of the British Academy—a gnal distinction—has been added to the many cademic honours which have been conferred on that eteran scholar, Prof. A. H. Sayce. He has also been warded the Huxley Memorial Medal of the Royal nthropological Institute for 1929, and invited to eliver the Institute's Huxley Memorial Lecture in 930. Prof. Sayce's long career—he is now in his ighty-fourth year, and has been a fellow of Queen's ollege, Oxford, since 1869—is a remarkable record f scholarship, both in the study and in the field. 'or to the long list of books and articles from his pen ealing with the archæology of the Near East, especi-lly as related to Biblical archæology, must be added is work as an explorer and excavator in Asia Minor, gypt, and other countries of the East which bear pon his special studies. His work in the decipher-ent of cuneiform and Hittite inscriptions will always e a monument to British scholarship in this branch f study. Yet notwithstanding the highly specialised haracter of his studies, his interests have always emained wide, as was shown by the "Reminiscences" ublished in 1923. It was probably a surprise to most of his readers to learn that he was nearly shot as a spy in the Franco-Prussian War of 1870.

THE Kelvin Medal Award Committee, consisting of the presidents of the leading British engineering institutions, after consideration of representations received from leading engineering bodies in all parts of the world, has awarded the Kelvin Medal for 1929 to M. André Blondel. The medal is awarded as a mark of distinction in engineering work and investigation of the kinds with which Lord Kelvin was especially identified. M. Blondel, as engineer of the Ponts et Chaussées since 1889 and for many years the chief engineer of the French lighthouse services, is distinguished by his work on signalling apparatus, both optical and electrical, and particularly for his investigations in connexion with electrical measuring apparatus and photometry. In 1913 he was elected a member of the Paris Academy of Sciences, and in 1923 was appointed Inspecteur Général des Ponts et Chaussées. M. Blondel is an honorary member of both the British and American Institutions of Electrical Engineers. This is the fourth triennial award

of the medal, which has in previous years been given to Dr. W. C. Unwin (Great Britain), Prof. Elihu Thomson (U.S.A.), and the Hon. Sir Charles Parsons (Great Britain).

THE new laboratory at the University of Sheffield for research on the cold-working of steel, opened on July 6, has been established in consequence of a generous gift from the Worshipful Company of Ironmongers of London, which made a grant of £800 a year for seven years to endow a fellowship and two scholarships in the cold-working of steel. To make this gift available, the firms connected with the cold-working industry have, through the Cutlers' Company of Hallamshire, presented the University with the necessary plant. The new laboratory will be attached to the metallurgical and engineering departments of the University, and will be controlled by the professors of those subjects assisted by a committee on which the Ironmongers' Company, the Cutlers' Company, and the industry will be represented as well as the University. The University is greatly indebted to Mr. Percy Lee, Master Cutler of last year, to whose initiative and energy the establishment of the laboratory is due.

THE mechanical equipment of the new laboratory includes a wire and bar drawing plant constructed by Messrs. George Crossley, Ltd., of Cleckheaton. Having a two-speed gear and variable speed motor, wire drawing speeds of from 28 to 360 feet a minute may be obtained, and wires can be drawn of all sizes up to $\frac{5}{8}$ in. diameter and rods up to 1 in. diameter. The heavy drawing block is fitted with a friction clutch drive and capstan type pull-in gear, which is also used for drawing steel bars, for which purpose a specially strong die stand is fitted at the end of the bench. The light wire block is fitted with the ordinary creeper drive, using spring shock-absorbing cushions. Capstan type pull-in gear is provided. The motor can develop 20 h.p. throughout its range of speed. The rolling mill plant has been constructed by Messrs. W. H. A. Robertson and Co., Ltd., of Bedford. It has hardened steel rolls of 10 in. diameter and 10 in. face, and is fitted with two-speed gear box and variable speed motor, giving a range of rolling speeds from 60 to 300 feet a minute. The motor is capable of developing from 50 h.p. at 570 r.p.m. to 120 h.p. at 1260 r.p.m. The lubrication is by Messrs. Robertson's patent 'Flood' system. Water cooling is provided for the rolls and roll bearings and for the oil in connexion with the lubrication system. An alternative set of rolls is fitted with 'Skefko' double roller bearings. The research laboratories of the Department are well provided with appliances for mechanical and physical testing of the cold-worked material, including a complete outfit for the study of deformation by the X-ray method.

THE *Bulletin* of the Physical Society for May contains abstracts of the papers communicated and the remarks made at the discussion on the teaching of geometrical optics held on April 26. Nearly thirty members took part, some engaged in teaching the subject in schools, others in university or technical colleges, and a few engaged in designing or constructing optical instruments. On the question of sign convention, there appears to be wide differences of opinion; some teachers take distances as positive when measured with the light stream, others positive against the stream; some make a converging lens have a positive, others a negative, focal length. The designers all appear to use the analytical geometry method, and in conformity with industry make the focal length of a converging lens positive. These sign conventions are the great stumbling-block in the way of pupils, one speaker stating that in a recent school examination 240 out of 244 candidates made mistakes of sign in a simple lens question.

THE vergence or convergence method of dealing with lens problems, which has been used in several German and at least one English book for thirty years or more and is free from many of the difficulties as to sign, was mentioned by one teacher only. The wave surface method introduced forty years ago was advocated by three teachers and by several speakers holding non-teaching posts, but was considered unsuitable by the majority of the school teachers. Many speakers stressed the necessity of bringing the pupil, whether in school or college, into contact with modern optical instruments. It must be very unsatisfactory to school teachers of the subject to find how frequently their pupils fail to understand the sign convention they use, and it is to be hoped that one result of the discussion will be the general adoption of some method which will produce better results than those brought before the meeting.

ON Monday, July 8, an interesting collection of exhibits was opened at the Science Museum, South Kensington, to illustrate the history of the famous Rainhill locomotive trials on the Liverpool and Manchester Railway, the centenary of which falls in October of this year. The three outstanding dates in the early development of the world's railway systems are Sept. 27, 1825, when the Stockton and Darlington Railway was opened; Oct. 6, 1829, when the competition between the *Rocket*, *Sans Pareil*, *Novelty*, and *Perseverance* began on the Liverpool and Manchester Railway; and Sept. 15, 1830, when that line was officially opened. The collection of engines and models in the locomotive section of the Museum is well known, but during the next four months additional exhibits, including portraits, models, drawings, and letters, will be shown, while the Museum authorities have constructed a full-scale model of Ericsson's *Novelty*, and Mr. Henry Ford is kindly lending the working copy of Stephenson's *Rocket* which he has had constructed for his Museum at Dearborn, Michigan, U.S.A. Railways came into use two hundred years ago; Trevithick made the first steam locomotive in 1804, Blenkinsop's engines were running in 1812, Hedley's *Puffing Billy* was built in 1813, and Stephenson's first engine in 1814. By 1829 about fifty locomotives had been made in England; two, which would not go, in Germany; and one, a mere model, in America. Even in 1829, however,

here was a difference of opinion about the merits of he locomotive, but the Rainhill trials settled the uestion once for all. The exhibition just opened hould prove of great interest to teachers giving lessons n industrial development.

A FURTHER contribution to the history of the ship as made by Sir Westcott Abell in a paper read at Newcastle on July 2 to a joint meeting of the North-East Coast Institution of Engineers and Shipbuilders nd the Institution of Engineers and Shipbuilders in cotland, entitled "The Story of Safety at Sea". Dealing with his subject under the headings freeboard egulations, subdivision into watertight compartments, nd life-saving appliances, he referred to the loading narks placed on the sides of vessels by the Venetian uthorities so early as A.D. 1000, and an appendix ives a chronology of safety regulations. The modern istory of the subject, however, begins with the action f the Committee of Lloyd's and the Liverpool Under-riters, who, about 1835, proposed rules governing ree board. The important work of the Royal Com-ission of 1873 came through the action of Plimsoll, ho took up the cause of sailors in unseaworthy ships, n the House of Commons. The various committees hich have sat under the guidance of Sir Edward Reed, Sir Philip Watts, Sir Edward Harland, and Lord Charles Beresford have dealt with various aspects of he matter; the First International Conference on the afety of Life at Sea was held in 1913, and the second net in April and May last. The latter was attended y representatives from fourteen maritime countries nd four Dominions and Colonies, and regulations were greed to for the subdivision and construction of ships s well as for life-saving appliances, navigation, and ireless. In some tabular matter accompanying his aper, Sir Westcott Abell states that the average umber of vessels lost annually during 1905–14 was 4, while the average during 1920–27 was only 18.

THE only paper read at the recent summer meeting f the Institution of Mechanical Engineers, held at Manchester on June 24–28, was that by Mr. R. W. Bailey on "The Contribution of Manchester Re-earches to Mechanical Science." Beginning with a eference to the work of Dalton, Mr. Bailey reviewed t some length the epoch-making investigations of oule on the mechanical equivalent of heat, and then assed on to the researches of Fairbairn, who was "a orn engineer, possessing all the qualities necessary for he execution of large enterprises, and although, per-aps, of limited technical attainments, he appreciated nd was able to employ them in others". Fairbairn's ollaborators included Eaton Hodgkinson and the athematician Thomas Tate. Hodgkinson's own work n cast iron is among the classics of engineering re-earch. The concluding part of the paper was devoted o the work of Osborne Reynolds, who, like Dalton and oule, "possessed the philosophic mind and a gift or demonstrating or investigating a phenomenon by imple and ingenious experiment". The full import f Reynolds's researches is only now adequately ap-reciated. Mr. Bailey also gave a sketch of the esearches conducted in the mechanical engineering departments of the University of Manchester and of the Manchester Municipal College of Technology. The paper as it has been published is illustrated by photographs and drawings, and contains a bibliography which in itself affords ample evidence of the great value of the research work done in the district.

MR. E. C. SNELGROVE completes an interesting account of two important irrigation schemes in the Bombay Deccan in *Engineering* for June 21. The first is on the River Pravara and the second on the River Nira, both of which rise in the Western Ghats. The scheme on the Pravara River included the erection of the Bhandardara Dam for impounding water in Lake Arthur Hill, while that on the River Nira included the erection of the New Bhatgar Dam for storing water in Lake Whiting. The rainfall on the Ghats reaches as much as 250 in. per annum, but it is confined to the four monsoon months. The Bhatgar Dam, which took sixteen years to build, is by far the biggest masonry dam in the world, while the Bhandardara Dam is only exceeded in height by the Pacoima Arch Dam, California. The Bhandardara Dam is 1663 feet long, 278 feet high above the lowest foundation, and cost £560,000, while the storage capacity of Lake Arthur Hill is 10,086 million cubic feet. The Bhatgar Dam, replacing an older dam of the same name, is 5333 feet long, 190 feet high, and contains 21½ million cubic feet of masonry, or nearly 3½ million cubic feet more than the Assuan Dam; it cost £1,170,000. Mr. Snelgrove compares the cost of these three great dams, and says that 100 cubic feet of masonry in the Bhandardara Dam cost £4, 13*s.* 4*d.*, in the Bhatgar Dam £5, 10*s.*, and in the Assuan Dam £12, 17*s.* 4*d.* He also says that protecting the land by irrigation increases its value by 200 per cent, and that while charges for water have increased by less than 40 per cent, the value of crops has increased by about 85 per cent.

THE *Himalayan Journal*, of which the first number is dated April 1929, is a periodical that is to be published from time to time by the Himalayan Club. This club, designed to bring together all those interested in travel and exploration in the Himalaya, was suggested so long ago as 1866, but the actual foundation dates from 1927. The club exists "to encourage and assist Himalayan travel and exploration, and to extend knowledge of the Himalaya and adjoining mountain ranges through science, art, literature, and sport". At its start it amalgamated with the Mountain Club of India, the foundation of which was contemporaneous. The club hopes to prepare route- and guide-books as well as scientific monographs. It has found temporary accommodation in the office of the Survey of India at Simla. The *Himalayan Journal* is edited by Major K. Mason, and contains a dozen important articles illustrated with photographs and maps. They include articles by Mr. F. Ludlow on the Shyok Dam in 1928; by Major K. Mason on the Indus floods and the Shyok glaciers; and by Mr. Kingdon Ward on botanical exploration in the Mishmi Hills. News of various

expeditions are also given. The journal has started with a high standard of achievement which promises well for future issues.

IN *A.E.G. Progress* for May an interesting account is given of a floating Diesel-electric power station. This station was built specially to help in the construction of a lock on an inland waterway near Berlin. The station is of 500 horse-power, and work on the lock has been proceeding continuously for the last eighteen months. Any disturbance to the smooth working of the water pumps used for draining would be very serious and would involve a heavy loss. In colonial countries, new power stations are sometimes erected on building sites of a swampy nature. In this case the outlay for the machine foundations is very costly. As the probable demand also is difficult to estimate, it seems to us that a floating power station would be very useful. It could be anchored in a river or in a sheltered sea bay, and the electrical possibilities of the site could be explored in a year or two and the ideal site for an electric power station to serve the neighbourhood determined. The advantages of a Diesel-electric unit are that it can be started almost at once and is always ready for service. These units can also be erected on pontoons. With four cylinder engines the vibration is noticeable but is not objectionable.

THE non-magnetic ship *Carnegie* left Yokohama on June 24; she is due at San Francisco about July 29. The vessel was at Pago-Pago, American Samoa, on April 1–5, and at Apia, Western Samoa, on April 6–20. Passing close to Wake Island on May 11, the vessel arrived at Guam on May 20 and left for Yokohama on May 25. The oceanographic observations are constantly developing new bottom features; among these was the discovery of a new deep which was named "Fleming Deep" by Captain Ault, the maximum depth recorded being 8650 metres at lat. 23·8° N. and long. 144·1° E. While in Western Samoa and in Japan the magnetic standards of the Apia and Kakioka observatories were compared with those of the *Carnegie*. Celebrations of the twenty-fifth anniversary of the research activities of the Carnegie Institution of Washington are to be held on board the *Carnegie* in San Francisco Harbour on Aug. 26, 27, and 28, just before her departure late in August for Hawaii, Samoa, and New Zealand.

AT its annual business meeting, held at Worthing last week, the Museums Association elected Dr. F. A. Bather as an honorary member in recognition of his distinguished museum work and of his services to the Association as president, as editor, and in other ways during the forty years of its existence.

THE earthquake which was felt in Gloucestershire on Tuesday, July 2, was recorded at Kew Observatory as an extremely small disturbance, which commenced at 20 hr. 27 min. 32 sec. G.M.T., and lasted about 30 sec. Five considerable earthquakes were recorded at the Observatory during the three days July 5–7. Four of these had epicentres in the North Pacific. The fifth, which occurred on the morning of July 6, originated in the Atlantic Ocean off the coast of Brazil.

THE Newcomen Society will hold its summer meeting jointly with the Devonshire Association at Dartmouth on July 23–26 to commemorate the bicentenary of the death of Thomas Newcomen. During the meeting a small collection of Newcomeniana will be on view in the Mayor's Parlour at the Town Hall. Wreaths will be laid on the Newcomen Memorial on July 23, when Mr. L. St. L. Pendred, president of the Newcomen Society, will deliver a eulogy, and Dr. G. P. Bidder, president of the Devonshire Association, will give an address on the same evening. Eng.-Capt. E. C. Smith is to deliver a public lecture on "Thomas Newcomen: Two Hundred Years of Steam Power" on July 25, and various local excursions have also been arranged. The honorary secretary of the Newcomen Society is Mr. H. W. Dickinson, Science Museum, South Kensington, London, S.W.7.

IN our issue of June 15, p. 926, in a paragraph on "Chemical Apparatus", it was stated that Messrs. Griffin and Tatlock, Ltd., combine the former business of John J. Griffin and Sons, Ltd., and Baird and Tatlock, Ltd. While this statement is perfectly correct, we are asked to point out that Messrs. Baird and Tatlock (London), Ltd., are not concerned in this merger.

Two very useful catalogues of science books have just been issued by Messrs. H. K. Lewis and Co., Ltd., 136 Gower Street, W.C.1. They range respectively over the subjects of mathematics, physics, astronomy, and the history and method of science, and botany, zoology, agriculture, and geology, and will be of service for reference. They can be had free upon application.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A junior lecturer in applied mathematics in the University of the Witwatersrand, Johannesburg—The Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, Trafalgar Square, W.C.2 (July 15). A visiting teacher of heat engines, at the L.C.C. School of Engineering and Navigation, High Street, Poplar, E.14—Education Officer (T.1a), The County Hall, Westminster Bridge, S.E.1 (July 15). Two temporary junior engineering assistants and a temporary architectural assistant—The Chief Engineer, Metropolitan Water Board, 173 Rosebery Avenue, E.C.1 (July 15). An assistant lecturer in pathology at the Welsh National School of Medicine—The Secretary, University College, Cardiff (July 15). A senior lecturer in chemistry at the Bournemouth Municipal College—The Director of Education, Town Hall, Bournemouth (July 16). A science master, with special qualifications in agricultural science, under the Magherafelt Regional Education Committee, Co. Londonderry—The Principal and Executive Officer, Technical School, Magherafelt, Londonderry (July 16). A taxidermist and preparator of specimens in the Auckland (New

ealand) Institute and Museum—The High Commissioner for New Zealand, 415 Strand, W.C.2 (July 0). Assistant civil engineers in Civil Engineer-in-hief's Department, Admiralty, and H.M. Naval stablishments at home and abroad—The Civil Engineer-in-Chief, Admiralty, London, S.W.1 (July 20). n assistant lecturer in zoology—The Registrar, niversity College of North Wales, Bangor (July 20). junior physicist at the Building Research Station, arston, nr. Watford—The Secretary, Department Scientific and Industrial Research, 16 Old Queen reet, S.W.1 (July 20). A demonstrator in zoology the Royal College of Science—The Secretary, mperial College of Science and Technology, South ensington, S.W.7 (July 23). A student probationer oologist or physiologist)—The Director, Marine iological Laboratory, Plymouth (July 25). A curator radium at the General Hospital, Birmingham—he House Governor, General Hospital, Birmingham uly 25). A lecturer in geology at Armstrong llege, Newcastle-upon-Tyne—The Registrar, Armrong College, Newcastle-upon-Tyne (July 27). An sistant chemist (woman) for the Air Ministry, Kidooke — The Secretary (I.G.), Air Ministry, W.C.2. physico-chemist at the Indian Lac Research stitute, for research work in the problems conected with harvesting, storage, manufacturing, d packing lac and shellac — "India", care of Messrs. Richardson and Co., 26 King Street, St. James's, London, S.W.1. A visiting lecturer in engineering science and a full-time chemistry master at the Borough Polytechnic Institute—The Principal, Borough Polytechnic Institute, Borough Road, S.E.1. A full-time teacher of general engineering subjects at the Acton Technical Institute—Mr. J. E. Smart, Municipal Offices, Acton, W.3. A part-time instructor in mechanical engineering at the Watford Technical School—The Principal, Technical School, Watford. Pathologists in Nigeria on the West African Medical Staff—The Private Secretary (Appointments), Colonial Office, 2 Richmond Terrace, Whitehall, S.W.1. An assistant experimental officer for design duties at the Government experimental establishment, Biggin Hill, Kent—The Secretary, R.E. Board, 14 Grosvenor Gardens, S.W.1. An expert in animal husbandry, and a director of the Agricultural Research Institute, Pusa, India—The Under-Secretary of State, Economic and Overseas Department, India Office, Whitehall, S.W.1. Two junior assistants, one in physics and one in chemistry, under the British Boot, Shoe, and Allied Trades Research Association—The Director of Research of the Association, 19 Bedford Square, W.C.1. A biologist at the Rothamsted Experimental Station for research work in general microbiology—The Secretary, Rothamsted Experimental Station, Harpenden.

Our Astronomical Column.

New Minor Planet.—A planet, the provisional signation of which is 1929*KA*, was recently disvered at Heidelberg; it had the unusually rapid otion of 27′ northwards per diem. Dr. G. Stracke ves an ephemeris in *Beobachtungs-Zirkular*, No. 23; magnitude is now 13·3 and is slowly diminishing. e states that the rapid motion arises from a comnation of great eccentricity and high inclination, the net being now near perihelion. Its position on ly 16 is R.A. $16^h\ 32^m{\cdot}0$; N. Decl. 5° 3′. It is then rly stationary in R.A. and is moving north 5′ daily.

Solar Activity.—Observations of sunspots and ulæ for the first half of 1929 show that the sun's ivity is definitely declining towards minimum, ich may be expected in about four years' time. another indication of the progress of the 11-yr. ar cycle, it may be noted that the shape of the ona seen during the total eclipse of May 9 last was intermediate type. Although the sun's activity is sening, occasional large sunspots may be expected. the preceding cycle, for example, the most extensive eam of spots seen for nearly half a century occurred 1920, three years after the maximum. A couple of ge spots have recently been seen together on the c, nearly on the same meridian but on opposite es of the sun's equator. Both were visible to the ked eye for a few days. Particulars of these spots given in the following table in continuation of t given in NATURE of Mar. 16, p. 425:

Date on Disc.	Central Meridian Passage.	Latitude.	Area on June 24.
June 18–30	June 24·0	9° S.	1/1350
June 18–30	June 24·5	13° N.	1/2000

(Areas express proportion of hemisphere covered.)

Catalogue of the Comparison Stars for Eros.—It is only a year and a half before the very near proach of Eros to the earth in January 1931. Prof. Kopff prepared a list of stars suitable for use as comparison stars on this occasion; many observatories have co-operated in observing them. Prof. P. Stroobant, Director of the Uccle Observatory, is one of the first to publish results. In Tome 2, Fascicule 2, of the *Annals* of the Observatory, he publishes the positions of about 400 stars, lying between north declinations 19° and 48°; these are the stars needed for the earlier portion of the apparition; Eros goes later into south declination, and the observation of the southern stars is more difficult for northern observatories. The magnitudes of the stars observed at Uccle range from 7·0 to 9·6. Some were observed eight times; a few were observed once only, but by co-operation of observatories good positions should be available.

Russian Society for the Study of the Universe.—The report for 1928 just issued by this Society gives details of remarkable activities shown in various branches of astronomical research. The number of members was 604, and 29 meetings took place. As an example of the work of the observing sections, it may be mentioned that 23 observers pursued solar inquiries and sent in 1789 drawings of groups and spots. Variable stars attracted 20 members, who obtained 7600 observations. The meteoric field had 30 observers, who gathered 17,200 records. The results obtained in the various departments appear to be of excellent character and extensive in amount. Fifteen volumes have been published by the Society, and the last one issued comprised 390 pages. Branches of the Society have been formed in the provinces, and these have already proved very successful in their work, as being of considerable assistance to the parent organisation at Leningrad. The marked increase in the number of members and subjects under investigation gives promise of the accomplishment of much useful research in various fields of astronomy.

Research Items.

Anatomy of Seals.—The structure of seals has been the subject of various memoirs, but none has been so thoroughgoing as A. Brazier Howell's account of the comparative anatomy of the eared and earless seals (*Proc. U.S. Nat. Mus.*, vol. 73, art. 15, 1928). The investigation is based upon *Phoca hispida* as representing the earless and *Zalophus californianus* the eared seals, but comparative references to the work of other anatomists are included. A few general results only can be mentioned. In spite of the efforts which have been made to link eared and earless seals with land mammals of the bear and otter tribes, Howell regards the evidence to be so indefinite as to preclude any reasoned conclusion as to ancestry. The methods of swimming now employed by the two groups of seals are fundamentally different, but many of the characters common to both may be largely due to convergence, although on the whole the earless seals exhibit in such characters a somewhat greater divergence from fissiped conditions than the eared. On the other hand, there are characters, such as the telescoping of the skull, the cartilaginous extensions of the digits, and the flatter phalanges, which suggest that *Zalophus* may have travelled further from the typical terrestrial carnivore. In both groups there are hints of structures in the limbs which suggest that a certain amount of retrogressive evolution may have taken place, *Phoca* at one period having perhaps made more use of its fore limbs, *Zalophus* of its hind limbs. But this suggestion requires more evidence and is put forward tentatively.

'Knothead' Carp.—Mr. David H. Thompson has investigated the causes of deformed carp in the Illinois River (State of Illinois Department of Registration and Education, Division of the Natural History Survey, *Bulletin*, vol. 17, art. 8, 1928). The carp of the Illinois River are of considerable importance commercially and the 'knothead' malformation is well known. The fish have bulging opercles, narrowed skull, and sunken cheeks, besides other irregularities, are pronouncedly sluggish in habit, and smaller than the normal form. Investigation of the gills showed a reduction of lamellæ and an altogether less effectual breathing apparatus than is shown in the ordinary healthy fish. No parasites were present nor other infection, but the flesh was very soft. It was found that these deformed individuals inhabit those parts of the river which are polluted largely by sewage with a consequent reduction of green algæ, and that there is apparently a direct relation between this reduction of algæ, containing vitamin D, and the malformed fish. It seems probable that the malformation is due to some external influence which has interfered with the developmental processes or the metabolism of the fish and has altered their growth form. The author concludes from his researches that the 'knotheadedness' is a disease similar to rickets in the higher vertebrates, due to lack of vitamin D. Other fishes of the area are not affected, probably because they are less tolerant of pollution than the carp and feed in the cleaner backwaters. Interesting radiograms are given of the heads of the normal and 'knothead' carp.

Development of a Hexactinellid Sponge.—Y. Okada describes (*Jour. Fac. Sci. Imp. Univ. Tokyo*, vol. 2, 1928) the development of a hexactinellid sponge, *Farrea Sollasii*. Material was obtained by monthly dredgings at about 150 fm. in the Sagami Sea. The author considers that the breeding period extends throughout the year. The oocyte is at first scarcely distinguishable from an archæocyte, but later becomes larger and lies in the outer trabecular layer of the sponge. After fertilisation it appears to migrate into the inner side of the trabecular layer and takes up its position near the wall of a flagellated chamber, where it undergoes its early development. The first two cleavages at least are total and equal. The blastula is planula-like, at first nearly spherical but later oval. The youngest embryo found in the trabecular layer consists of an outer layer of closely packed cells and a central mass of jelly-like substance containing numerous amœboid cells which have wandered in from the outer layer. Six stauractin spicules are present. In a later stage with twelve spicules, flagellated chambers appear in the central mass—each chamber is due to the amœboid cells having become rounded and arranged round a central cavity. Coincident with the formation of flagellated chambers an invagination appears on the surface of the young sponge—probably the commencement of the communication between the chambers and the exterior. The collars and flagellæ probably develop after the embryos are set free. The development of the spicules is described. The six rays of the hexactin do not grow in a single cell as in other siliceous sponges but from a syncytial scleroblast mass. The nuclei of this mass are more than six and bear no definite relation to the rays. The hexactines originate as such.

***Echinococcus* in New South Wales.**—Ian Clunies Ross records (*Sydney University Reprints, Series* I, Agric. and Vet. Sci., 1927) the results of an investigation into the occurrence and distribution of *Echinococcus granulosus* (*Taenia echinococcus*) in New South Wales. Of 18 cattle examined, six were infected with hydatids (two in the liver and four in the lungs); of 123 sheep 41 were infected (liver 12 times and lungs 33 times). Of twenty-three dogs examined at the slaughter yards in four country districts, seven were infected with the worm, but more than one hundred dogs from the city and suburbs of Sydney were examined and no infestations were observed. The records of four district hospitals chiefly between 1911 and 1924 show that out of about 19,000 patients 71 were infected with hydatids. In a south coast district there were ten persons infected with hydatids in a total of 1370 in-patients at the local hospitals. In man, cases of hydatid in the liver greatly outnumber those in which the lungs are affected.

Hawaiian Non-Marine Mollusca.—The molluscan fauna of Hawaii has been studied for many years, but the literature is very scattered. Mr. E. L. Caum has, therefore, rendered very real service in compiling a "Check List of Hawaiian Land and Fresh Water Mollusca" (*Bernice P. Bishop Mus. Bull.*, 56). This list is systematically arranged with abbreviated references to sources for which a key is supplied at the end, and also an alphabetical list of all the names from orders to species, exclusive of synonymous generic names. It is a most valuable piece of bibliographical work, and more such are wanted.

Removal of Chlorosis in Fruit Trees.—The phenomenon of chlorosis (or scarcity of chlorophyll) is not uncommon on calcareous soils, and it is generally recognised that it is usually due either to scarcity of available iron or to immobility of this metal in the plants. In commercial practice it is not always easy to remedy the condition. This is most often done by spraying with iron salts, and more than half the pineapple crop in Hawaii has to be treated in this way.

Wallace (*Jour. Pomology and Hort. Sci.*, **7**, 251-260), ntinuing his investigations on chlorosis of fruit ees, now finds that much more certain improvements n be produced by growing cover crops over the ots of the affected trees. Any danger of nitrogen arvation can be removed by suitable fertilisers.

Non-Dehiscence of Stamens in Punjab-American ttons.—This phenomenon, which was observed by evor Trought, the Cotton Research Botanist at allpur, and is described in the *Memoirs* of the Dertment of Agriculture in India, Bot. Ser., vol. 17, o. 1, 1928, may prove of general importance, as der these conditions the flowers are not fertilised, d are shed after a few days. With American cotton the Punjab at certain times of the year the anther every stamen fails to open. In this preliminary per the cause for this failure to dehisce is left open, t the author is evidently inclined to attribute it to failure of the pollen grains to swell up to their rmal size at maturity. Incidentally, he gives asons for thinking that the text-book mechanism dehiscence through the hygroscopic qualities of e wall of the fibrous layer does not account for the rmal dehiscence of the anthers in cotton.

A Haploid Tomato.—In the last few years, haploid utations or plants with a single set of chromosomes ve occurred in the experiments of several different vestigators. A haploid *Datura* arose in 1922 among e offspring of certain plants which had been subcted to cold, by Blakeslee. Other cases have been scribed since in tobacco (*Nicotiana tabacum*), wheat *riticum compactum*), *Solanum ringrum*, and *Crepis pillaris*. These have usually occurred in the F_1 neration of a species-cross involving more or less erility. A haploid tomato mutant has recently been scribed by Lindstrom (*Jour. of Heredity*, vol. 20, o. 1). It appeared in the F_2 of a variety cross in nich there was complete fertility. It was dwarf, th shorter, thinner stem, much smaller leaves and wers, and almost completely sterile, since its twelve romosomes had no mates. In the pollen mother lls there is no attempt at pairing of the chromosomes, d they separate in various irregular ways. In the ot tips, occasional cells had the diploid number. uttings made from the original plant through six nerations of cuttings numbering more than 300 ants have shown no fertility and no reversion to the ploid number of chromosomes. It may be signifint that, of the six haploid mutants now known, all t two belong to the family of the Solanaceæ.

Annual Periodicity of Earthquakes.—In a paper blished in the recent number of the *Bulletin* of the ismological Society of America (vol. 18, pp. 246-6; 1928), Dr. C. Davison considers the annual riodicity of earthquakes in relation to geographical nditions and the intensity of the shocks. It is own that, throughout the vast continental areas of th hemispheres, the maximum epoch of the annual riod in earthquakes of semi-destructive or less insity falls during the mid-winter months. These eat areas are, however, fringed by certain insular d peninsular regions in parts of which the maximum och is reversed. On the other hand, the annual riodicity of great destructive earthquakes in either misphere is independent of geographical conditions. e maximum epoch occurs in the summer months, ether the regions are continental, peninsular or ular.

Miocene of Northern Colombia.—The marine Mioe strata of northern Colombia, now described by F. M. Anderson (*Proc. Calif. Acad. Sci.*, Ser. 4, vol. 18) extend eastwards from the Gulf of Urabá along the Colombian coast to the Sierra Nevada de Santa Marta and are found again near Rio Hacha, whence they extend southwards into the valley of the Rio Cesar. The author briefly describes the several subdivisions and considers that they correspond fairly well on the whole with those of Santo Domingo. Of the fossil contents, 170 species of Mollusca and three Foraminifera are enumerated, almost without regard to any scheme of taxonomy. Thirty-seven new species and one new name are included and figured on sixteen very good plates.

Post-Tertiary Marine Mollusca of Oahu.—Limestone formations fringe the shore line of the Hawaiian island of Oahu above tide mark and extend for miles inland. From a study of their fossil contents, J. M. Ostergaard considers that their age is not greater than the Pleistocene (*Bernice P. Bishop Mus. Bull.*, 51). Details of the twenty-two collecting stations are given and their positions shown on a text map, with a table of the fossil occurrences at them. Eighty-two species and subspecies of mollusca were determined, of which three are presumably extinct. These last, as well as some forms living elsewhere than at Hawaii, are fully described and figured. The author discusses certain problems concerning the distribution of Indo-Pacific forms and concludes, in view of the fact that many species now found thriving best in the warmer Indo-Pacific are represented in Hawaii by fossils only, and others by species on the border of extinction, that when the limestone was forming Hawaii had a higher ocean temperature.

Oil-fields of Burma.—Dr. L. D. Stamp has been indefatigable in his efforts to make known more widely the oil geology of Burma, which, it must be admitted, since the well-known publications of Sir Ernest Pascoe, has been somewhat of a closed book to all save those concerned with actual developments. Two years ago Dr. Stamp dealt with the conditions governing the occurrence of oil in this territory; this was followed last year by his paper on the connexion between structural features and commercial oil deposits, in which Burma also figured prominently; and now we have a paper on the actual oil-fields themselves, read to the Institution of Petroleum Technologists on April 9. It is creditable to the author that he has been able to deal with his data in such a way that there is comparatively little overlap between the three papers, though one wonders why he did not present this last subject as a natural continuation of the first, as most of the facts must have been available to him at that time. However, this discussion of the chief oil-fields and their geology is timely and will be useful to students and others who have long felt that some authoritative account of this important oil-producing region of the British Empire should be available, particularly as the official volume referred to was published so long ago as 1912. The account of the oil-fields is not only technical, but also economic, and in every case an interesting summary of developments by the varied interests concerned is given. The author expresses the opinion that, while existing fields in Burma have prospects of good reserves and long life, there are small hopes of extensive new fields.

Ozone in the Atmosphere.—In *Smithsonian Miscellaneous Collections*, vol. 81, No. 11, 1929, F. E. Fowle discusses measurements of the ozone content of the earth's atmosphere made at the Smithsonian solar radiation observatories. Cabannes and Dufay showed in 1926 that the published coefficients of

atmospheric transmission obtained by Smithsonian observers revealed ozone absorption in the Chappuis band (4500-6500 A.) in the visible spectrum, in remarkable agreement with the characteristics of this band as measured by Colange in the laboratory. Fowle has applied this method to the original observations, in more detail than was possible with the published data alone. He is thus able to examine the amount and variation of ozone at the Smithsonian stations, using data totally independent of those on which the work of Fabry, Dobson and their collaborators is based, since the latter refers to the Hartley band (2300-3100 A.). For Table Mountain results from both methods are available; they agree in the mean values, and the variations found in the two ways are closely correlated, but those obtained by Fowle's reductions are the greater. Further, Fowle finds a distinct correlation between ozone content and the annual mean sunspot number for the northern stations, though not for Montezuma in Chile; Dobson found very little connexion of this kind. Fowle raises the question whether the ozone absorbing in these two bands may be in different molecular states, produced by different agencies and possibly situated in separate layers of the atmosphere.

Infra-Red Spectra.—The first two papers by Dr. E. K. Rideal and his collaborators in a projected series on infra-red spectra appear in the June issue of the *Proceedings of the Royal Society*. In the first, by C. P. Snow and A. M. Taylor, a grating spectrometer is described, and the particular points to which attention had to be directed in its construction are set out. The chief of these are efficiency between 2 μ and 6 μ, dispersion and resolution sufficient to effect fine structure analysis of the order of one wave-number, and adaptability for absolute measurements of absorption. In the second, by F. I. G. Rawlins, E. K. Rideal, and C. P. Snow, an account is given of the results obtained in the investigation of the 5·3 μ band of nitric oxide with this instrument. The spectrum includes a Q branch, as would be anticipated from the gyroscopic nature of the molecule NO, which is of the odd-electron type, and has also the expected steady change in intensities in bands of low rotational quantum number. There is, in addition, close agreement between the magnitudes of the molecular constants as deduced from this part of the spectrum, and those obtained from the electronic band-spectra, the two values given for the moment of inertia of the normal molecule, for example, being $1{\cdot}64 \times 10^{-39}$ gm. cm.^{2} and $1{\cdot}63 \times 10^{-39}$ gm. cm.^{2} respectively. Work is now in progress on the 4·7 μ band of carbon monoxide, and has already shown, contrary to a previous statement, that this does possess a fine structure.

Scattering of Electrons.—A paper by N. F. Mott in the June number of the *Proceedings of the Royal Society*, on the scattering of fast electrons by atomic nuclei, contains some interesting remarks on the physical significance of some of the quantities that enter into the equations of the new mechanics. The special problem considered is the existence of a spin axis in an electron. When the electron is part of an atom, it evidently cannot be dealt with individually. When it is free, on the other hand, the 'uncertainty principle' shows that the two obvious methods of testing for whether or not it has magnetic moment, namely, by the use of a magnetometer, or by the setting up of a Stern-Gerlach deflection apparatus, must also fail. There are, nevertheless, two constants in the mathematical expression for an electron which might be taken to define an axis, and the question becomes one of finding if these can appear in the solution of any experimental problem involving an electron in such a way as to be recognisable. Mr. Mott finds that this can be answered in the affirmative; when an initially unpolarised beam—that is, one in which the supposed axes are orientated at random—is scattered from two targets in succession, its intensity will be asymmetrical about the direction in which it falls on the second target, and this should be detectable experimentally. The actual formula which is derived for single scattering does not agree very well with the experimental results of Chadwick and Mercier, but it is possible that the discrepancy is due to the neglect of the radiative forces upon an accelerated electron.

Synthesis of an Isomeride of Thyroxine.—Since the constitution of thyroxine was elucidated in 1926, a number of its derivatives have been prepared and their physiological activity examined. The *Journal of the Chemical Society* for May contains an account of the preparation by Harington and McCartney of the preparation of $\beta\beta$-di(3 : 5-di-iodo-4-hydroxyphenyl)-α-aminopropionic acid

$$[(OH.C_6H_2I_2)_2CH.CH(NH_2).CO_2H],$$

which is isomeric with thyroxine. This substance differs from thyroxine in that the benzene rings are connected by a carbon instead of an oxygen linkage, but it retains the characteristic *o*-di-iodophenolic grouping. The new compound does not appear to show any physiological activity of the type exhibited by thyroxine.

Dissolution of Silver in Water.—According to a paper in Collection I., No. 3, of *Czechoslovak Chemical Communications*, Křepelka and Toul have found that pure silver dissolves slightly in distilled water and passes into solution in the form of silver ions. The greatest concentration of silver found by nephelometric measurements was 0·037 mgm. in 1000 c.c., and this amount was reached after about 21 days; further contact of the metal with water did not increase the concentration above this figure. When the surface of the metal had been reduced with hydrogen and the water freed from dissolved gases, the silver did not dissolve in sufficient quantity to be detected. It is concluded that the dissolution is due to a surface film of oxide or adsorbed oxygen, or to oxygen dissolved in the water. When the measurements were made using glass vessels, the amount of silver dissolved was about 0·003 mgm. more than when silver apparatus was employed. This difference is probably caused by alkalis from the glass.

A Transformation of Austenite into Martensite.—A paper by Dartrey Lewis, of more than usual interest, was presented at the recent meeting of the Iron and Steel Institute. A 0·8 per cent carbon steel may be quenched in a molten salt-bath at 232° C. to an austenite which is stable for at least five minutes. On subsequent cooling to room temperatures, the austenite is converted into martensite, the final hardness of which is practically independent of the rate of this cooling. Such a two-stage hardening should have commercial application in the treatment of steel since the quenching can be placed under full control and the rate at which the martensite is formed varied. Such treatment should be of value in the avoidance of quenching cracks and distortion. Further, the possibility is opened up of conducting forming operations at this temperature whilst the steel is still ductile, and then allowing the parts to harden on cooling in air.

Annual Conference of the Museums Association.

THE fortieth annual conference of the Museums Association, held at Worthing on July 1–5, was many respects the most successful in the history that body. The success was due to many favouring cumstances. The Royal Commission on National iseums and the Miers Report on Provincial Museums d awakened the interest of a wider public; hints om the Commission that the national establishments ght be helped to give more practical shape to their knowledged sympathy with the local museums, as ll as the bodily presence of two Carnegie Trustees th their secretary, roused the hopes of curators; e nearness to London enabled many busy people attend and contribute papers; and, above all, e choice of Sir Henry Miers for president promised practical address and a fruitful discussion.

A main object of the Association is to promote -operation between museums of every kind. Sir enry Miers took that as the subject of his address, d speakers had been chosen to approach it from rious sides. Sir Henry has in mind a museum rvice for the whole country, parallel to the library rvice that has cast a net which now gathers in en small villages. As driving force for such a heme he sees only the Museums Association. With all means the Association has already done much, t voluntary labour, manifesting its results only in e annual conference, the *Museums Journal*, and a w circulating collections, is no longer enough. A ntral office and a whole-time secretary are urgently eded, and to provide these more museums should me in. There is too much individualism and competition, too little co-operation and mutual aid between museums; the larger museums do not realise w much they stand to gain by helping their weaker ethren. Sir Henry indicated many openings for -operation, among them the guidance of archæological excavation, the interchange of loan exhibits, d the training of curators.

In the ensuing discussion, Dr. Cyril Fox extended e idea of co-operation to the overseas members, d showed how ethnographical material stored in r museums might now be of more use if returned the Dominions whence it came long ago; he suggested a central clearing-house for archæological jects. The Earl of Crawford, comparing museums, cture-galleries, and libraries, pointed out that the blic appreciation of museums called for greater ental effort; the three classes should be put on a vel, since each is necessary for intellectual progress. r. A. J. K. Esdaile urged the need of a central fice for arranging exchanges and exhibitions. Mr. ate Regan thought that junior members of museum affs should be welcomed to the Association at a smaller subscription but without the *Journal*. Dr. F. A. Bather replied that this would not help the juniors so long as their superiors did not encourage them to attend the Conference. As for a central clearing-house, the best course would be for each department of the national museums to receive and distribute its own class of material, but much could be done directly if use were made of the *Journal*. Other speakers advocated the extension of regional federations under the auspices of the Association.

The discussion was revived later by Dr. Hay Murray's suggestion that every large museum should adopt a small museum, and was carried further by Mr. Lawrence Haward's account of the scheme of loans initiated by the late C. Rutherston's bequest to the Manchester Art Gallery, by Major Longden's informative paper on exhibitions of foreign art, and by a most vigorous address from Dr. G. H. Locke, public librarian of Toronto, on co-operation between libraries and museums. Mr. Eric Maclagan here arrived to explain the kind of help the Victoria and Albert Museum could give to provincial museums, and reopened the discussion on training.

Most of the remaining papers dealt with the educational work of museums. Mr. Harold L. Madison, curator of education at the Cleveland (Ohio) Museum of Natural History, gave a thoughtful and instructive address on the work of his museum in connexion with schools. Miss Bertha Hindshaw related the efforts of the Ancoats Museum, Manchester, to get hold of the 'young visitor' from that poor district. Sir William Furse explained how he had managed to get the numerous small-scale panoramas which add so greatly to the attraction of the Imperial Institute Galleries. Mr. C. A. Siepmann, of the British Broadcasting Corporation, made a suggestive speech on the relations between broadcasting and museums, and this also provoked an animated discussion.

The more technical papers included a demonstration by Mr. W. E. Mayes of making wax models of plants, and notes by Mr. J. Ritchie on the preservation of ancient tempera paintings and on celluloid mounts for insects and herbarium specimens.

After so much time given to papers, the delegates enjoyed a visit to Tarring Cottages and Cissbury Camp, the latter admirably elucidated by Mr. T. Sheppard, and a whole-day excursion to Arundel Castle, Goodwood House, Chichester, Bignor Roman Villa (explained by Mr. S. E. Winbolt), and Petworth House. The remarkably smooth working of the excursions, as of all the other arrangements, was due to the organising capacity of the local secretary, Miss Marian Frost, of the Worthing Museum, aided by the ladies of her staff.

Biology of Norwegian Lakes.

BRAARUD, B. Föyn, and H. H. Gran, in a recent paper entitled "Biologische Untersuchungen einigen Seen des östlichen Norwegens August–ptember 1927" (Norske Videnskaps-Akademi i lo, I. Mathem. Naturvid. Klasse 1928, No. 2), report several lakes in the east of Norway with regard to e plankton and its environment. The work was rried on in a similar way, but for a longer period, the Hurdals-See in 1926, and the results published this same publication (1927). In the Hurdals-See e temperature, oxygen content, hydrogen ion concentration, and distribution of the plankton were vestigated at different depths from May to October, the preserved plankton centrifuged and estimated quantitatively side by side with living net-plankton estimated qualitatively, the result showing that most of the species were in largest numbers in summer with a maximum in August–September. Only *Dinobryon sertularia* formed a maximum in June.

The other lakes, and also the Hurdals-See again, were worked in August and September 1927 with the same methods and apparatus. The plankton of the Hurdals-See was poorer than in 1926, probably because of the very wet summer.

Amongst the nine lakes in question, the Haugatjern was distinctive in having large masses of plankton

made up of few species occupying the opaque upper layers, a strong oxygen deficit in the depths and below six metres, and definite differences in the hydrogen ion concentration between the upper and deeper layers. Such conditions can only be explained by a strong food stream from land. The plankton production of the Haugatjern is as much as 100 to 1000 times greater per surface unit than any of the other lakes. These lakes are different from one another in several ways, and the amount of plankton varies much in the different lakes. The renewing of the plankton food on which the plankton production depends comes either from the upper layers, by supply from land, or from the depths by vertical circulation. In those lakes where the flowing water in summer must always be comparatively poor in nourishment, the circulation of the food-stuffs for plankton production is more important than the supply from outside. In shallow lakes in summer a daily vertical circulation is possible by the warming of the bottom by radiation, and otherwise in spring and autumn layers are quickly mixed so tha maxima are formed of quick-growing planktoni species.

Such distinct maxima at special times of year ar to be expected, especially in shallow lakes. In th deeper lakes the circulation is slower and seasona maxima not so distinct. Thus the differences in th richness of the plankton in those lakes, other tha the Haugatjern, can probably be explained best b the fact that the relative richness in the shallowe lakes is conditional on a quick circulation of the food stuffs present.

The species which take part in the mass produc tion are few. They include Cyanophyceæ, Chloro phyceæ, Flagellata, Dinoflagellata, and Diatomaceæ The diatoms, especially *Asterionella gracillima* an Cyanophyceæ (*Anabæna flos aquæ* and *Cœlosphærium Nægelianum*), are very quick-growing. Of the dino flagellates, *Ceratium hirundinella* is universally pres ent, reproducing in masses in the Haugatjern.

Agricultural Afghanistan.[1]

THE Institute of Applied Botany (Leningrad) sent an expedition to Afghanistan in 1924, consisting of the director of the Institute, Prof. N. I. Vavilov, the engineer-agronomist, D. D. Bukinich, and the agronomist, V. N. Lebedev. The principal purposes of the expedition were: (1) To investigate and collect plants cultivated in the country; (2) to ascertain the regularities in the distribution of crops and their varieties over the slopes of the Hindu Kush; (3) to investigate the technique of local agriculture, the irrigation in particular; (4) to gather information as to the agricultural resources, especially as regards cotton-growing.

The expedition travelled about 6000 km., covering the whole territory of agricultural Afghanistan. The authors divide Afghanistan into six climatic regions: (1) Mountain regions with cold and temperate climate and well-marked differences between the seasons. (*a*) High mountain regions 2400 m. above sea-level, with 7-9 months of winter. This is the region of spring cereals, chiefly of irrigated crops. The highest altitudes are characterised by a dry desert climate. (*b*) Regions of temperate climate situated between 1300 m. and 2400 m. above sea-level. This region is chiefly characterised by irrigated winter wheat, and irrigated cultivation generally. (2) The lowland regions below 900 m. (*c*) Desert regions with small amount of rainfall (less than 250 mm.), very hot summers and cold winters. (*d*) The region of steppes and foot-hills. The summer is hot, with average temperature above 25° for the warmest month. This is a region of non-irrigated crops. (*e*) The lowland of Yalalabad with subtropical, comparatively moist climate. (3) The median zone from 900 m. to 1300 m. (*f*) Desert regions with very small amounts of rainfall and cold winters.

The soils of Afghanistan may be divided into four groups: (1) Heavy loams peculiar to swampy river valleys, chiefly in rice-growing regions; (2) medium loams of the slopes; (3) loess-like loams of the foot-hills; (4) the 'irrigation' soils of the oases.

A characteristic feature of Afghanistan is the co-existence of extremely primitive forms of husbandry with rather intensive forms of farming in the oases, which may be observed in the valley of Hari-Rud, especially near Herat. Agriculture of the valley is characterised by extraordinary diversity of crops. The methods of irrigation are thoroughly worked out cereals are harvested twice a year, and manuring i extensively practised.

The most isolated and unexplored region of Afghanistan is Kafiristan. High up in the thickets of mountain forests, the population practises a sedentary type of agriculture. Fearing the hostility of neighbours the agricultural population of Kafiristan lives on inaccessible heights. Mills are found everywhere; the plough—where possible. In places some excellently cultivated terraces of crops may be observed. Every foot of soil is utilised.

The study of Afghanistan by the expedition has established the dependence of water sources on meteorological conditions. This is naturally unfavourable to agriculture, which is adapted to the rainfall; thus the increase of acreage under winter crops depends on the rainfall in autumn.

Three principal types of irrigation were observed: (1) Source irrigation, (2) kiarese irrigation, and (3) river irrigation. The acreage of irrigated lands in Afghanistan is estimated by the authors as approximately half a million hectares, that of cultivated lands as one and a half million hectares, and the area of 'bohara' as approximately 500,000 hectares. The most wide-spread method of irrigation is with running water. Three peculiarities are noted in the native methods of irrigation: the primitive construction of the main water-carrying canals, and the good condition of small irrigation networks, and the elaborate implements used in preparing fields for irrigation.

The first place in cultivation in Afghanistan is taken by wheat, the second by barley, the third by rice. Then follow the Leguminosæ, and the next place is occupied by cotton. A considerable acreage is under alfalfa and *Trifolium resupinatum*.

The Hindu Kush dividing Afghanistan determines the general progress of agriculture from the low periphery to the main mountain range, and distinctly shows the regularities in the vertical distribution of the crops over the mountain zones. The authors give a table of the extreme elevation reached by different plants of Afghanistan under conditions of cultivation: hull-less barley, 3400 m.-3000 m.; 2500 m.-3000 m., hulled barley, peas, spring rye, *Ervum Ervilia*. This is, on the whole, the zone of spring cereals and of grain Leguminosæ. At 1500 m.-2000 m., the majority of cultivated plants appear. This is the zone of maximum diversity of crops and varieties. Grapes may be regarded as the determining plant of the zone. 1000 m.-1500 m. is the principal zone of cotton, rice,

[1] Supplement 33rd to the Bulletin of Applied Botany, of Genetics, and Plant-Breeding. Agricultural Afghanistan. (Composed on the Basis of the Data and Materials of the Expedition of the Institute of Applied Botany to Afghanistan.) By Prof. N. I. Vavilov and D. D. Bukinich. Pp. iii+610+xxxii+28 plates. (Leningrad.) In Russian, with summary in English.

ucurbitaceæ. Below 1000 m. subtropical crops rive: sugar-cane, oranges, the date palm.

The study of the separate crops is discussed in great tail in eight special chapters. The investigation varietal diversity of cultivated plants has shown at Afghanistan and adjacent countries, especially e North-Western Provinces of India, is one of the ost important primary world agricultural centres, here the varieties of numerous plants have originated. his is objectively proved by varietal diversity of a ries of crop plants and by the coincidence of the ea of the varietal diversity of many most important uropean crops. For example, as regards the versity of club wheats and soft wheats generally, ghanistan occupies the first place in the world. hough the varietal diversity of cultivated barley is or, *Hordeum spontaneum* grows abundantly in rthern Afghanistan, while eastern Afghanistan, and e adjacent regions of north-western India, are the rld centre where the maximum of characteristics of e most important Leguminosæ are found. The region probably the centre of origin of these crops. Many demic forms have been found. In regard to flax, ghanistan undoubtedly borders on one of the incipal centres where the forms of this crop have iginated. Hemp in south-eastern Afghanistan re-esents the pro-genital type of *Cannabis indica* Lam. series of oleiferous Cruciferæ have evidently inde-ndently become cultivated field crops of Afghanistan d adjacent countries. Northern Afghanistan is the alm of wild melon, with all transitions to the culti-ted type, and there is no doubt that Afghanistan is art of the primary area in which cultivated melon s originated. The extraordinary wealth of varieties carrots, turnips, and radishes show that Afghanistan the primary world centre of these crops. The same ay be observed with regard to other less important ps, such as spinach.

The botanico-geographical facts definitely direct tention to the south-eastern part of Afghanistan d regions towards the Punjab. It is in this region at the complex of genes of many European-Asiatic ps have been found. Here, and in the adjacent tricts, a series of crops have originated, a fact oved by the presence of all stages of evolution. e above-mentioned region includes the Punjab. is to this small part of India that we turn for the ution of the genesis of the above cultivated plants d not to the rest of India, which has no bearing on e majority of these crops. In regard to climate, ief, and crops, the North-Western Provinces form e undivided whole with Afghanistan. The re-ining part of India differs sharply from Afghanistan climate and soil.

At the end of the book the authors give a detailed scription of the route travelled by the expedition, th the indication of distances, the character of ndscape, short agronomical notes on the region, the scription of the road, and altitudinal data. Good ps are given illustrating geographical, orographical, logical, vegetational, and agricultural divisions of ghanistan. Most of the photographs in the book very interesting, but poorly reproduced.

University and Educational Intelligence.

LONDON.—Sir Gregory Foster has been elected e-chancellor for the year 1929–30.

The following doctorates have been conferred:—*Sc. in Biochemistry:* Mr. H. J. Channon, an internal dent of University College, for a thesis entitled The Unsaponifiable Fraction of Liver Oils"; *D.Sc. Statistics:* Miss E. M. Newbold, an internal student of University College, for a thesis entitled "Practical Applications of the Statistics of Repeated Events, particularly to Industrial Accidents"; *D.Sc. in Anthropology:* Mr. W. J. Perry, University reader in cultural anthropology, for a thesis entitled "The Children of the Sun".

A SHORT account is given in *La Nature* for June 1 of the inauguration and development during the past hundred years of the well-known École Centrale des Arts et Manufactures of Paris, the principal technical institution in France for training students for private industrial works. Founded by the four savants, Théodore Olivier, a mathematician, Eugène Péclet, a physicist, Phillippe Benoit, a mechanician, and the famous chemist J. B. Dumas, with whom was associated an administrator, Alphonse Lavallée, the school was authorised by the Minister of Public Instruction on Dec. 23, 1828, and its first session opened on Nov. 20, 1829, with 145 students. Its early career was threatened at first by the political upheaval of 1830 and then by the cholera epidemic of 1832, but it gradually grew in importance and in 1862 became a recognised government establishment. Housed at first in the old Hôtel de Juigné, it now occupies a fine block of buildings in the quadrilateral formed by the streets named after Condé, Montgolfier, Berthoud, and Vaucanson, just behind the Conservatoire National des Arts et Métiers. When Lavallée retired from the directorship, the well-known French engineer August Perdonnet succeeded him, while to-day the destinies of the school are controlled by M. Léon Guillet. During the War, between four and five thousand old students of the School served as officers in the French army, while the handsome memorial gateway at the School is to the memory of some five hundred of them who fell on the field of battle.

A FURTHER stage in the development of one of the oldest technical colleges in Great Britain was marked by appropriate ceremony on June 13, when the recently completed extension of the Wigan and District Mining and Technical College was opened by Viscount Chelmsford. The College dates back to 1857, when it began as the Wigan Mining and Mechanical School, which occupied a single room in the Mechanics' Institute and boasted 50 students. It was in 1903 that the present College buildings were opened, and in 1919 a temporary annexe was erected: this was in use until 1921, when the allocation of £32,000, together with £5000 for equipment, by the Miners' Welfare Fund, allowed the erection of the present permanent extension in its place. At the opening ceremony, the chair was taken by the chairman of the governing body, Mr. J. T. Gee, and, after Viscount Chelmsford's address, he, Mr. A. M. Lamb, vice-chairman of the governing body, and Mr. G. H. Winstanley, were presented with the honorary diploma of the College in mining. Speeches were made by Mr. J. T. Browne, president of the Lancashire and Cheshire Coal Association, Mr. J. McGurk, president of the Lancashire and Cheshire Miners' Federation, the Mayor of Wigan (Councillor P. Murphy), and Mr. P. E. Meadon, Lancashire County Director of Education. The work of the College, under Principal J. F. S. Ross, falls into four main categories: full-time courses of university or equivalent standard, full-time junior schools (technical and commercial), part-time day courses, and evening courses in a great range of subjects. The College, which stands on an island-site, has now about 110 rooms, which include nearly 30 laboratories, 9 workshops, 5 drawing offices, and many lecture- and class-rooms.

Calendar of Patent Records.

July 14, 1730.—On July 14, 1730, a patent was granted to Captain Robert Hamblin, a shipowner of Lynn, for "a new method for distinguishing of lights, whereby one light erected for the guidance of shipping may be perfectly known from another, and consequently every ship's crew be informed what coast they are off". The invention was, however, held to be an infringement of the powers of Trinity House, and the patent was revoked. Hamblin also financed the first light-ship, which was established at the Nore in 1732 by David Avery, and again brought him into conflict with Trinity House. The Admiralty agreed, however, that tolls might be levied although the ship itself should become the property of Trinity House.

July 14, 1808.—The bobbin-lace machine, the foundation of a large industry, was invented by John Heathcoat, whose first patent for the invention was sealed on July 14, 1808. The first factory was set up by Heathcoat at Loughborough, but this was attacked and the machinery destroyed by the Luddites in 1816, and the manufacture was transferred to Tiverton, where the firm is still operating.

July 15, 1846.—An early example of the 'pedrail' system of locomotion is shown in the specification of Edmund Leahy's English patent, which was enrolled on July 15, 1846. The invention is described as for the purpose of easing the motion and reducing the friction of wheels of carriages while passing over irregular surfaces, and consists in the "adaptation of a series of short rails to the wheels, which rails are linked together in a manner resembling an endless chain, arranged on rollers round the peripheries of the wheels".

July 15, 1869.—Margarine was the invention of the French chemist, Hippolyte Mège, and was patented in France on July 15, 1869, and in England the same year. The manufacture received a great impetus during the Franco-Prussian war, and was rapidly developed.

July 16, 1867.—One of the earliest systems of reinforced concrete was due to Joseph Monier, a gardener of Paris, who was the first to make extensive use of reinforced concrete and was mainly responsible for its general adoption. His French patent was granted on July 16, 1867, and the new method of construction was firmly established by the German firm of Freytag und Heidschuch, which purchased the German and Austrian rights.

July 17, 1790.—The English patent granted to Thomas Saint, a cabinetmaker of London, on July 17, 1790, contains the earliest description of a sewing machine. The machine, which is for sewing leather for boots and shoes, makes a chain-stitch, and has a perpendicular action, automatic feed for the material, and an eye-pointed needle.

July 18, 1783.—John Broadwood's piano patent, which is dated July 18, 1783, revolutionised the construction of the early square piano and represents an important step in the history of the instrument. Broadwood placed the tuning pins at the back of the case instead of as usual at the right-hand side, and added dampers and pedals. The construction was copied by all the leading makers, including those of Germany.

July 18, 1833.—On July 18, 1833, a patent was granted to Francis Maceroni for his steam-carriage, which had a multi-tubular boiler with fan-draught behind the carriage, and a horizontal two-cylinder engine below the body. A carriage was built in 1833 and ran between Edgware and Paddington for some time, attaining an average speed of 10 miles an hour. Carriages were also sent to Paris and Brussels, where they were received favourably.

Societies and Academies.

London.

Geological Society, May 29.—**K. S. Sandford**: The Pliocene and Pleistocene deposits of Wadi Qena and of the Nile Valley between Luxor and Assiut (Qau). Wadi Qena is a broad and deep dry valley which joins the Nile from the north at Qena, about 40 miles north of Luxor. The oldest beds visible within the walls of the valley system are of Pliocene age, deposited in a gulf of the Mediterranean. This had been cut by river erosion during the elevation of the Egyptian plateaux in Miocene and (in the south) partly in Oligocene times, and it was then flooded to a height of at least 550 feet above present sea-level. A non-fossiliferous series of strata was deposited in it. Great thicknesses of travertine are locally present in the series. Re-elevation carried the flooded valley system back to fluviatile conditions in Plio-Pleistocene times, accompanied by the irruption of enormous quantities of detritus from the Red Sea Hills. In Pleistocene times an ordered succession of river terraces was laid down in the Nile valley and in all the major wadis. Thereafter (in Upper Palæolithic times) desert conditions began to assert themselves, and the Nile alone survived. At about the same time the Nile carved a deep channel and re-excavated the deeper parts of the Pliocene-filled Miocene gorge. The process of filling this up still continues.

Mineralogical Society, June 11.—**E. J. Wayland** and **L. J. Spencer**: Bismutotantalite, a new mineral from Uganda. This was found in a pegmatite vein at Gamba Hill, about 35 miles north-west of Entebbe. The large rough crystals, weighing up to a kilogram or more, are orthorhombic with a habit and axial ratios similar to those of columbite. Analyses made by Mr. W. O. R. Wynn at the Imperial Institute give the formula $Bi_2O_3.Ta_2O_5$, analogous to stibiotantalite ($Sb_2O_3.Ta_2O_5$).—**L. Hawkes**: On a partially fused quartz-felspar rock and on glomero-granular texture. In a partially melted granite, fusion began at the quartz-felspar contacts. It is suggested that the temperature was raised above the eutectic point but not to the melting-point of any of the constituent minerals, and that a granite of quartz-orthoclase-albite eutectic composition will melt completely in the dry state below 950° C. Coarse-grained granites may exhibit a segregation of quartz and felspar, revealed in section by monomineralic areas of several grains in anhedral intergrowth. The name 'glomero-granular' is proposed for this texture, which may result from the normal undisturbed crystallisation of the magma.—**P. Marshall**: The occurrence of a mineral hitherto unrecognised in the phonolites of Dunedin, New Zealand. A mineral with low birefringence and low refractive index, hitherto taken to be either nepheline or sodalite, is distinct from these and nearer microsommite or davyne. It is usually allotriomorphic but also occurs as very small (0·15 mm.) hexagonal prisms. Analyses of hydrochloric acid solution of phonolites containing this mineral to the exclusion of other soluble silicates, indicate that it is a sodium aluminosilicate loosely combined with sodium chloride. The mineral stains dark violet when treated with silver nitrate. The name proposed for the mineral is ameletite.—**G. T. Prior**: The meteoric stone of Lake Brown, Western Australia. The stone, weighing when found 4·75 kgm., has been known since 1919. Chemical analysis and microscopic examination prove it to be an intermediate hypersthene-chondrite of Baroti type.—**I. de Finály** and **Sándor Koch**: Fülöppite, a new Hungarian mineral of the plagionite-

emseyite group. This was found at Nagybánya, Hungary [=Baia Mare, Rumania] as small monolinic crystals of the plagionite habit. Analysis shows t to be an acid member of the group with the formula $PbS.3Sb_2S_3$. Associated with it is an acicular probably orthorhombic) lead-antimony mineral with he composition $3PbS.4Sb_2S_3$, which is compared vith the Bolivian keeleyite.

Optical Society, June 13.—**W. M. Hampton**: The eam given by dioptric apparatus. The light in the xial direction given by a lighthouse lens using a hite source can only be white if the source is greater han a certain limiting size. For such sources a simple xpression is deduced for the axial beam candle-power or revolving lenses. A graphical method is given for omputing the candle-power of smaller sources. The ffect of the dispersion of the glass of the lens on the naximum distance at which satisfactory candle-power eadings can be made is considered. A general solution is obtained for the intensity of light of any colour n any direction and at any distance when using fixed enses.

Royal Meteorological Society, June 19.—**F. J. W. Whipple**: Potential gradient and atmospheric pollution; the influence of 'summer time'. The Kew Observatory records for periods before and after 1916 ave been compared. There are normally two scillations of potential gradient in the 24 hours; the arly morning minimum and the forenoon maximum ere both advanced when 'summer time' came in, hereas the second oscillation of the day was reduced n amplitude.—**A. J. Bamford**: Vertical air-currents s measured by pilot balloons. The results of the last even years' pilot balloon observations at Colombo now that in the first half kilometre the average rate f ascent is considerably faster than the theoretical ate given by the Dines formula, while in the next alf kilometre it is appreciably less than this value. his can be reconciled with a general atmospheric novement that is, on the whole, upwards in these ayers, by accepting the idea that tropical convection ccurs in the form of large rolling whirls of at least a ilometre in diameter, the effect of such whirls being o displace balloons from the ascending side towards he descending side after they pass the level of the entre. The next part of the paper deals with cases here the simple whirl system is complicated by nonsoonal and other circulations, and the last part eals with observations up to ten kilometres.—**George later**: Studies on the Rhone glacier, 1927: the relationship between the average air-temperature and he rate of melting of the surface of the glacier. Work n Spitzbergen suggested the following formula: M = thickness (in feet) of ice melted per month 30 days) and t = average monthly temperature (° F.), $M = (t - 32)/2$. This gives 0·2 inches of ice melted per ay for each degree (F.) above zero under normal tmospheric conditions, wind and rain producing eviations from the normal. The relationship was onfirmed by observations on the Rhône Glacier in 927 over a period of twenty days. The average temeratures (July 26 to Aug. 15) used were: Maximum 0·6° F., minimum 34·5° F., noon 43·79° F., giving a aily average of 8·8° F. above 32° F. Assuming the ate of 0·2 inches of ice melted per day for each degree, he total amount melted would be 35·2 inches, which confirmed by actual measurement.

PARIS.

Academy of Sciences, June 3.—**Ch. Achard and M. nachesco**: Chloride elimination in acute diseases and s relations with the acid-base equilibrium.—**Georges Claude**: The utilisation of thermal energy. Directing attention to a suggestion published by d'Arsonval in 1881 for the utilisation of the energy of hot springs with sulphur dioxide as the working fluid.—**E. Bataillon**: The physiological condition of male and female stereomitoses in the immature eggs of Anoura.—**Achille Le Bel** was elected a free Academician in the place of the late Marshal Foch.—**André Blondel**: A new method for the laboratory study of the beams of optical apparatus.—**J. Neyman**: A method of verification of hypotheses.—**V. Fock and D. Iwanenko**: Linear quantic geometry and parallel displacement.—**N. Cioranesco**: The method of Riemann for systems of equations of the second order.—**Jacques Chokhate**: The summation of certain series of integrable functions. Application to orthogonal functions.—**Paul Lévy**: The influence of the arguments of the coefficients on the growth of integral functions.—**J. Haag**: The elastic suspension of pendulums.—**Emile Belot**: The forms and evolution of the terrestrial mass before its spheroidal condensation.—**Thadée Banachiewicz**: The correction of orbits with the aid of co-ordinates referred to the plane of the movement.—**E. Prévot**: The determination of the international zero of altitudes, taking into account the law of variation of the mean annual level of the sea.—**Alex. Véronnet**: The electronic theory of the ether and electromagnetism.—**Henri Chaumat**: An electrostatic machine giving continuous current.—**Daure**: The comparative study of the Raman spectra of some hydrogen compounds. From the comparison of the Raman spectra of more than forty compounds, all in the liquid state, it is concluded that although it is not possible to interpret the Raman spectra of all compounds by their molecular constitution, it is possible in the limited field of hydrogen compounds alone empirically to connect certain lines with particular linkages in the molecule.—**Bourguel**: A relation between the boiling point and the molecular structure of cis-trans ethylenic saturated and acetylenic acids. The boiling points of acids containing from four to nine atoms of carbon, saturated, cis and trans ethylenic and acetylenic acids are given both in tabular and graphical form. Certain regularities appear in the latter and these are summarised.—**F. Bourion and Ch. Tuttle**: The cryoscopic determination of the molecular equilibria of resorcinol in aqueous solutions of sodium chloride.—**Maurice Fallot**: The magnetisation coefficient and structure of gelatine solutions. The curve showing the coefficient of magnetisation as a function of the concentration consists of two straight lines, with a sharp angular point at 0·8 per cent of gelatine. This concentration was also found by Marinesco to correspond to a sudden change in the dielectric constant. These results confirm the view (Smith) that gelatine can exist in two molecular forms in solution.—**Maurice François**: The action of gaseous ammonia on mercuric bromide and chloride.—**Ch. Courtot and J. Pierron**: Contribution to the study of the α-ethylenic chlorides and alcohols.—**A. Mavrodin**: The action of organomagnesium derivatives on ethyl ethylcyanacetate.—**L. Berthois**: The heavy minerals of the eruptive and crystallophyllian rocks of Brittany. Detailed study of occurrence and morphology of the zircons and tourmalines. A study of these in a disintegrated rock may give useful indications as to the nature of the mother rock (granites, granulites, gneiss or mica schists).—**Marcel Casteras**: The western termination of the Massif of Arize and the structure of the secondary deposits of the neighbourhood of Saint-Girons (Ariège).—**Auguste Chevalier**: An ancestral form of the cultivated *Arachis*.—**Paul Genaud**: The exchanges of ions between yeast cells and solutions of ammonium chloride.

From the experimental data given it is concluded that the law of mass action is capable of accounting for the equilibria between a living cell and the solution in which it is placed.—**E. Blanchard** and **J. Chaussin**: The influence of a complete manure on the osmotic pressure in some agricultural plants. The special action of potash manures. The more rapid development of certain plants (oats, beetroot) under the action of manures coincides with a greater osmotic pressure in the interior medium, and the potash manures (sylvinite and potassium chloride) play a special part in this effect.—**Maurice Parat**: The active chondriome of the animal cell and the phenomena of pachynesis.—**Raymond-Hamet**: Some pharmacological properties of the alkaloid of *Banisteria Caapi*.

CAPE TOWN.

Royal Society of South Africa, Mar. 20.—**James Moir**: Colour and chemical constitution (26). (*a*) Pigments of yellow flowers, (*b*) addenda to previous parts. The first portion deals with flavone and its derivatives the yellow flower-pigments: a miscellaneous part follows dealing with (*a*) 'loading'-phenomena, (*b*) analogues of the quinoline-cyanine dyes, and some interesting little-known colour phenomena.—**Sir Thomas Muir**: Note on the Lagrangian of a special unit determinant.—**S. H. Haughton**: Notes on the Karroo Reptilia from Madagascar. Redescriptions of material in the Paris Museum. All the genera fall within the order Eosuchia, which is redefined; and two main lines of descent from *Youngina* within the order are indicated.—**K. H. Barnard**: A study of the genus *Colophon* (Coleoptera). The genus is essentially a mountain form, living on the summits of the peaks, and is flightless. Only two species were known, one of which has never been rediscovered since its description in 1855. Five new species have now been discovered.—**S. Schonland**: The South African species of *Rhus*, L. There is comparatively little diversity in the flowers of our *Rhus*. Inflorescences and fruits yield distinctive characters in many cases, but on the whole one has to rely on vegetative organs, which, however, vary often on the same plant within wide limits. The plant is usually unisexual, and male and female plants are sometimes different. Further, coppice shoots often show distinctive features. Interspecific hybridisation is not uncommon.—**F. E. Fritsch** and **Florence Rich**: Contributions to our knowledge of the freshwater Algæ of Africa. (8.) Bacillariales (Diatoms) from Griqualand West. In point of actual abundance, Diatoms form an important part of the algal flora of Griqualand West, but the actual number of species present is small. The total number here recorded is 72, of which 5 are new, while 4 new varieties are described. There are 25 new records for South Africa.

CRACOW.

Polish Academy of Science and Art, Mar. 8.—**W. Swietoslawski, Z. Blaszkowska**, and **E. Jozefowicz**: The boiling-point method of determination of the constant of chemical equilibrium.—**W. Swietoslawski** and **J. G. Zawidzki**: The application of reduced equations in chemical kinetics.—**L. Marchlewski** and **J. Meyer**: The absorption of ultra-violet rays by certain organic substances. The substances under examination included derivatives of furfurane, and isomeric bisubstituted benzene derivatives.—**J. Wasowicz**: The limits of perpetual snow in the Cordilleras of Alaska and Canada.

April 8.—**C. Fuja**: The formation and development of the stems and roots on the isolated cotyledons of *Cucurbita*, *Cucumis*, and *Lupinus*.—**S. Maziarski**: The striated ramified muscular cells in the liver of spiders.—**J. Wiszniewski**: Two new species of rotifers: *Pedalia intermedia* and *Paradicranophorus limosus*.—**M. Gieysztor**: Contributions to the knowledge of some species of Rhabdoceles belonging to the genera *Dalyellia*, *Castradella*, *Castrada*.—**S. Wisniewski**: The genus *Archigetes*: its anatomy, histogenesis, and biology.—**W. Szafer**: The flora of Poland.

May 6.—**T. Wazewski**: The change of the variable in simple integrals.—**Ladislas Natanson**: Certain properties of groups of waves.—**Nalini N. Bosc**: Fourier's series subjected to a quantic condition.—**Satyendra Ray**: (1) The regressive wave. (2) The generalisation of the virial of Clausius. If the pressure of the gas is not uniform but varies in the neighbourhood of the vessel walls according to a fixed law, the equation of the virial still holds good.—**L. Kwiecinski** and **L. Marchlewski**: The absorption of ultra-violet rays by benzene.—**L. Marchlewski** and **B. Skarzynski**: The absorption of ultra-violet light by certain hormones and by some analogous substances.—**R. Malachowski**: The constitution of anhydrotricarballylic acid.—**F. Poznanski**: The reactions of nitrous acid and of the diazo compounds on the substances contained in plants.

GENEVA.

Society of Physics and Natural History, April 18.—**Sw. and Th. Posternak**: The configuration of inactive inosite. By controlled oxidation of inosite with alkaline permanganate, the authors have obtained allomucic acid. This result, taken in conjunction with the optical properties of certain natural inositophosphoric esters previously described by the authors and by Anderson, leads to the selection for inactive inosite of that one of the seven stereochemical formulæ predicted by the theory which shows five hydroxyl groups on the same side of the plane of the ring, the sixth being found on the opposite side. The formation of ribosophosphoric acid of the nucleotides at the expense of the monophosphate of inosite, by the opening of the ring, becomes probable. This throws some light on the obscure question of the physiological rôle of inosite.

May 2.—**L. Duparc**: The geology of the lower Congo (left bank of the Niari). The author has prospected a region situated to the west of Mindouli. Two formations were found: the limestone schist at the base, supporting, sometimes discordant, red grits (Kundelungu). Two systems of orthogonal folds, east-north-east and north-north-west, were verified, the crossing of which gave rise to formation of domes.—**M. Gysin**: Some optical properties of mucic acid. The author has successfully applied Fedorow's method and the usual petrographic methods to crystals of mucic acid of very small dimensions ($60 \times 15 \times 10$ microns). He has proved a very strong double refraction $n_g - n_p = 0{\cdot}33$ and an angle for the optic axes $2V = -75°$.

May 16.—**L. Duparc, P. Wenger**, and **Ch. Cimerman**: The combination of nitrogen with manganese. The authors have studied the part played by the five following factors on the course of the reaction: the composition and origin of the manganese, temperature, duration of the reaction, pressure, catalyst. For the last two the results are new: the nitrogen fixed increases with the pressure and lithium nitride used as the catalyst increases the fixation of the nitrogen and accelerates the dissociation.—**A. Jayet**: The presence of old glacial and interglacial formations in the northern part of the Canton of Geneva. The author has found a typical base moraine covered by stratified clays. The latter in turn support a recent moraine. The old moraine has never been distinguished in visible outcrop except by excavation. Up to the present, only two moraines have been proved in the

asin of Lake Geneva.—**R. Wavre**: The second approxiation in the investigation of the free surface of the anets. The author continues the study of the form the exterior surface of stars in rotation by the ethod indicated in an earlier note. He makes a ore extended investigation in which the terms of the cond order are not neglected and gives the results very lengthy calculations, giving the Newtonian otential on the polar axis and the flattening of the uipotential surfaces.

ROME.

Royal National Academy of the Lincei, April 7.—**. Giorgi and A Cabras**: Relativistic questions on the roofs of the earth's rotation. Nordmann has recently ated that, in the light of modern physics, it is as gitimate to regard the stellar universe as rotating ily round the earth as to consider that the earth volves about its axis. The author discusses this uestion and concludes that the earth is endowed ith rotation with respect to local inertial axes. Of alileo's proofs, those of generic character deduced om considerations of symmetry in the distribution velocity throughout the whole of the stars are really alid, as well as the specific proof derived from the ll of weights from a tower. To these are to be added oucault's proof, gyroscopic proofs, Michelson and ale's experiment, and, though less directly, those epending on centrifugal force.—**Q. Majorana**: Photoectric thallium cells. Rolla and Mazza's claim to riority as regards these cells is disputed. The disovery of such cells is due to Case (1920), but an xact and detailed process for preparing them was rst published by Majorana and Todesco (1928).—**. Cambi and A. Clerici**: Reactions between ferrous ompounds and nitric oxide. The results of experients on the interaction of iron nitrosulphate and kali hydroxide indicate that the decomposition of is complex proceeds according to the schemes: >Fe . NO] $\longrightarrow$ $2[Fe'''] + N_2O$ (1) or $2Fe''' + \frac{1}{2}N_2 + NO$) or $2Fe'' + 2NO$ (3). Decomposition (1) occurs uantitatively in an alkaline medium and only as a econdary reaction in presence of acid; in neutral olution in presence of $Ag^{\cdot}$ the same reaction corresponds with the formation of silver hyponitrite. The issions (2) and (3) take place in acid media, the rmer predominating, as is shown by the fact that he ratio between the numbers of nitrogen atoms as $_2$ and as NO tends towards unity, whilst the ferrous on undergoes progressive reduction. Reactions nalogous to the above are observed in the action NO on ferrous carbonate, bicarbonate, and phosnate.—**G. Cimmino**: Extension of Picone's identity the more general ordinary linear differential uation.—**Pia Nalli**: Parallelism and geodetic coordinates.—**E. Bortolotti**: Congruence stars and solute parallelism: geometrical bases of a recent eory of Einstein.—**G. Mammana**: Decomposition of omogeneous linear differential expressions into symlic factors of the first order.—**M. Picone**: Addition the note: Demonstration of a theorem of analysis ed in plane physics.—**L. Toscano**: Dual formulæ Newton.—**L. Onofri**: Series of powers which assume e circumference of convergence as a singular line.—**Natta and L. Passerini**: Spinels of the type $e_2''Me^{IV}O_4$. Results are given of the examination means of X-rays and by the powder method of agnesium and cobaltous orthostannates, Mg_2SnO_4, d Co_2SnO_4, prepared by calcining the products tained by precipitating with alkali hydroxides lutions containing one molecule of stannic chloride d two molecules of magnesium or cobaltous chloride. baltous orthostannate crystallises in the cubic stem, and the unit cell, containing eight molecules, has the side $8{\cdot}605 \pm 0{\cdot}005$ A. and the volume $637{\cdot}16 \times 10^{-24}$ c.c.; the röntgenographic density is 6·307, the experimental value being 6·108. The magnesium salt is isomorphous with the cobaltous compound, the cell having the side $8{\cdot}580 \pm 0{\cdot}007$ A., and the volume being $631{\cdot}63 \times 10^{-24}$ c.c.; the röntgenographic density is 4·864, and the experimental density 4·738. Calculation of the structure factor shows that the space structure of these compounds belongs to the type 8*f*, 16*c*, 32*b* (space group O_h^7) and corresponds with that of the spinels. For the parameter *u* defining the position of the oxygen a value approximating to 1/8 is found.—**V. Caglioti**: Polyhalides (1). Chloroiodic acid, $HICl_4$, $4H_2O$. This acid may be obtained by adding finely divided iodine to concentrated hydrochloric acid and passing chlorine through the liquid until the iodine dissolves completely. The deep orange-red solution thus formed is converted almost entirely into crystals of chloro-iodic acid when immersed in ice.—**G. Malquori**: The systems $Al(NO_3)_3 - Fe(NO_3)_3 - H_2O$ and $KNO_3 - Fe(NO_3)_3 - H_2O$ at 0° and 40°. Neither at 0° nor at 40° does nonahydrated ferric nitrate form additive compounds or mixed crystals with either potassium nitrate or nonahydrated aluminium nitrate.—**A. Occhialini**: Length of the lines in the spectrum of a spark in relation to the concentration of the element. Experiments on various nickel and lead-tin alloys show that observation of the length of the spectral lines of the spark furnishes a rapid means for the quantitative analysis of alloys.

Official Publications Received.

CATALOGUE.

Catalogue of Fine Chemical Products for Laboratory Use: including Organic and Inorganic Chemicals, Analytical Reagents, Standard Stains, Indicators. (July.) Pp. 130. (London: The British Drug Houses, Ltd.)

Diary of Societies.

MONDAY, JULY 15.

EGYPT EXPLORATION SOCIETY (at Royal Society), at 5.—Dr. H. Frankfort: The Winter's Work of the Society (Lecture).

TUESDAY, JULY 16.

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section).—Visit to the Works of Messrs. J. S. Fry and Sons, Ltd., at Somerdale, near Bristol.

WEDNESDAY, JULY 17.

NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS (Associates' and Students' Section), at 2.30.—Visit to Seghill Colliery.

PUBLIC LECTURE.

TUESDAY, JULY 16.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, at 5.—Sir Thomas Lewis: Observations Relating to the Mechanism of Raynaud's Disease (Victor Horsley Memorial Lecture).

CONFERENCES.

JULY 12 TO 14.

MIND ASSOCIATION (Annual Meeting) (jointly with Aristotelian Society) (at University College, Nottingham).

Friday, July 12, at 8 P.M.—Prof. F. Granger: Probability and Paradox.

Saturday, July 13, at 10 A.M.—Prof. G. E. Moore and H. W. B. Joseph: Indirect Knowledge.

At 2.—Prof. J. Laird, C. E. M. Joad, and Miss L. S. Stebbing: The Present Position of Realism.

At 8 P.M.—J. D. Mabbott, H. H. Price, and G. Ryle: Negation.

Sunday, July 14, at 2.—Prof. G. Dawes Hicks, Prof. B. Edgell, and Prof. G. C. Field: Immediate Experience.

At 8 P.M.—Address.

JULY 13 TO 20.

ROYAL SANITARY INSTITUTE (at Sheffield).

In Sections devoted to Preventive Medicine, Architecture and Engineering, Maternity and Child Welfare (including School Hygiene), Hygiene of Food, Hygiene in Industry, Veterinary Hygiene, Representatives of Sanitary Authorities, National Health Insurance Services, Medical Officers of Health, Engineers and Surveyors, Sanitary Inspectors, Health Visitors (including Personal and Domestic Hygiene).

JULY 23 TO 26.

BRITISH MEDICAL ASSOCIATION (at Manchester).

Public Library

The Future of Agriculture.

A REMARKABLE suggestion has lately appeared in certain well-informed quarters of the American press, namely, that there are far too many farmers, that there is even now considerable over-production of farm produce, with still greater potential risk of such over-production, and that the only real remedy, drastic as it may appear, is the return of millions of farmers and their families to city life and work—if it can be found. It is estimated that there are about 6,500,000 farmers now engaged on American soil, but only a mere fraction of these are really efficient, up-to-date, prosperous, and contented; and the vast majority, more than five millions of them, have a desperate struggle to make a living. A vigorous agricultural deflation programme is seriously recommended.

It is very doubtful if such a proposal, though backed by many plausible and at first sight very convincing arguments, will prove very acceptable either to the farmers themselves or to the general American public. The latter, from President Hoover downwards, has for at least twenty-five years past constantly and consistently called for a vigorous and far-reaching policy of 'back to the land'. It has, of course, always been firmly held by a certain and predominating type of mind, especially of the physiocratic sort, that a numerous and, if possible, prosperous peasantry or yeomanry is a basic factor in national strength and balance; and if, as is generally assumed, it be the only or the most important source of the stronger and more vigorous elements in national life, there is much to be said in its favour. However, the most favourable ratio between town and country, between the agricultural and industrial parts of the population, is a highly complex problem and cannot be fully discussed here; although one may pertinently inquire if England, for example, is weaker because nine-tenths of its population is urban.

In America it has scarcely been seriously questioned that a large farming community is a necessary condition of strength. 'Back to the farm' has been a national cry, despite the terrible crisis of 1920–21. The farmers have been looked upon as constituting one of the largest and most valuable parts of the home market: a view which has also been consistently held in Great Britain, not without a tinge of envy at America's supposed very favourable position in this respect.

This complacent state of mind has now suffered a severe shock. Of the 6,500,000 farmers in the United States, it is alleged that only about one-

eighth, or say 800,000, have taken full advantage of the most advanced scientific methods and use of machinery. The others, constituting the vast majority, are, it is stated, hopelessly inefficient and on the brink of destitution and ruin. If this be true, it is a really remarkable state of affairs in view of the present position of agricultural education, both in theory and practice, in the U.S.A. After so many years of continuous and high pressure endeavour on the part of nearly every responsible person in America—statesmen, economists, social reformers, educationists, the all-powerful ubiquitous press—to foster and perfect agricultural education and bring the benefits of the latest research to the most remote corner of the country, is it possible, one may well inquire, that five million American farmers remain inefficient and unprosperous? Further, what have the makers of farm machinery, of concentrated fertilisers, of improved, selected seeds, and other farm requirements, been doing all this time?

The worst of the tale is, however, not yet unfolded. Over-production with low price level is held to be the root cause of the American farmer's plight to-day, and notwithstanding the voluminous flood of legislation, aiming at his assistance and relief, starting with the Fordney Emergency Tariff Bill and finishing up with the luckless and oft-defeated McNary-Haugen Bill, and the more recent and ambitious Farm Board proposal, there is little hope of real remedy except in a drastic reduction in the number of farmers. At least that is the view which appears to be gaining ground in some quarters. Then, if this be so, not only are we to believe that the great majority of American farmers are backward and inefficient, but also that it is, in a sense, fortunate that they are so! If all of them became as up-to-date as the small minority, then production and output would reach such vast proportions, and prices would fall to such extremely low levels, that the plight of the farmers would be far worse than it is now.

A pretty dilemma, to be sure, and a very curious paradox; not exactly gratifying to the protagonists of agricultural research and of improved methods, or to the sellers of machinery and fertilisers. It forms a strange commentary also on Sir Daniel Hall's presidential address on food and population to Section M (Agriculture) of the British Association in 1926. As a specific illustration the case of wheat has been taken. The present production of wheat in the U.S.A. is about 800,000,000 bushels per annum, which means a low average yield of no more than 13 bushels to the acre (as compared with about 32 in England and 41 in Denmark). Of this amount, about 200,000,000 bushels is exported. It is assumed, perhaps a little rashly, that under improved methods the yield per acre could be doubled. Modern science can doubtless do much, but still the law of diminishing returns is even so not yet quite obsolete and still operates though sometimes very much in the background; and it does appear a rather hazardous assumption to suppose that the yield of American wheat per acre could be doubled and at a lower or equal unit cost. But without quibbling about the precise increase possible under better methods, even a 50 per cent increase would be disastrous, since there is already over-production with present yields.

The further assumption is made that no great extension of demand is possible either in the home market or in the export trade. The American citizen is not likely to be able or willing to eat more, and in fact the modern tendency under the latest nutrition and hygienic teaching is to eat less, so that the branches of agriculture devoted to the production of human food cannot look for much increase in demand in the home market. As for the export trade in food, this is already declining in the direction of Europe, and despite recurring famines and a more or less chronic state of malnutrition near approaching starvation in many parts of India and China, these poverty-stricken parts of the world cannot afford a larger share of American agricultural abundance at prices satisfactory to the American farmer. In regard to the production of raw material, such as cotton, it is likewise assumed there is little prospect of substantial increase in demand.

It is therefore concluded that the only true remedy is a large reduction in the number of farmers. Whether this means that the farms so abandoned are to go out of cultivation or are to be absorbed by the minority of efficient and prosperous farmers is not quite clear; but apparently the great bulk of the land would have to go out of cultivation, since, if worked by the successful farmers, output and over-production would be on so vast a scale as to be unthinkable. It might be possible, perhaps for a few of the inefficient farms say up to 100,000, to join the present 800,000 but no more. Hence the only possible solution appears to be the removal of about 5,000,000 farmers from their present homesteads to the cities, that is to say, an exodus from farm to city of approximately 14,000,000 persons.

It looks as if such a drastic 'remedy' would involve greater problems and difficulties than those

ready existing. It is pointed out, however, that ie absorption by manufacturing industry in the ties of such a vast number would not be more fficult, if spread over a period of ten or more years, an the like absorption of about one million im-igrants from Europe every year before the quota olicy was introduced. Also, there is already in vidence a certain migration of population from ie country and farm life to the towns, especially nce the disastrous farming years 1920 and 1921. is estimated that, since those years, about four illion persons have returned to the cities ; and immigration could be still more rigorously re-ricted, this transfer could be greatly accelerated.

The position of American agriculture, as above escribed, contrasts strongly with the interesting iesis discussed by Sir Daniel Hall in his presidential ddress to which reference has already been made. n that address he presented data showing that the verage consumption of food and raw material by hite peoples requires from 2 to 2½ acres per head ; lso that the white population of the world is in-reasing at the rate of about five million per annum, nvolving a commensurate increase in cultivated nd of 12½ million acres per annum, or alternatively proportionate increase in yields on the existing rea, since there are no new areas worth speaking to be opened up. The only way to meet the nhanced demand for farm produce is by means of ore intensive culture, more scientific methods, nd in particular the much more considerable use synthetic fertiliser.

This, of course, may still remain true as the ex-ression of a general tendency for the greater part the world which is bound to operate in the long n ; but if the American position is really that hich has just been described—namely, over-roduction even though the great majority of the rmers are producing at a very low level—then it ould seem that the general rule enunciated by r Daniel Hall appears to be subject to substantial cal or temporary checks ; although, on the other and, it is quite possible that the American position as not been quite correctly diagnosed, and certainly me rather large assumptions have been made. ne may yet conclude that the bounty of Nature nd science is far greater than we have ever en-saged in our wildest dreams, that the law of minishing returns may be suspended almost definitely, and that there is—and will be for me time—an economic limit to the extent to hich the world, as a whole, can employ the mighty owers and resources of modern science in the alm of agriculture.

A Philosophy of Biology.

Theoretische Biologie. Von J. von Uexküll. Zweite gänzlich neu bearbeitete Auflage. Pp. x+253. (Berlin : Julius Springer, 1928.) 15 gold marks.

THIS is a really great book, well worthy of close study not only by biologists but also by all scientific men. For is not biology the science of life, and the first and most fundamental question raised by that science is " What is life ? " The author endeavours to look this question, and the other far-reaching questions which arise out of it, fairly in the face, and it is then seen that not only is biological science in the narrower sense involved, but also all other science of every description. Life is primarily our own existence, and secondarily the nature of other ' things ' in which we suspect an existence in some respects at least similar to our own. The first problem presented, therefore, to biology is the analysis of our own existence.

All science, physics and chemistry no less than biology, consists in the study of ' phenomena ', that is, of ' appearances ' to our conscious minds, and the question to be settled is how much of the ' appearance ' is due to the structure and working of the mind itself, and how much to an event independent of the mind. In endeavouring to answer this question, Uexküll affirms, and in our judgment quite justly, the soundness of the position taken up by Kant in the " Critique of Pure Reason ". He endeavours to extend Kant's theses. Kant asserted that space and time, which enclose within them all phenomena, are ' forms ' which our mind imposes on phenomena, and Uexküll not only reasserts this, but also adds to it that colour tone and odour are equally mental constructs, as are concepts of motion, including wave motion, and what the ' thing-in-itself ' would be like when stripped of these mental accretions no human being can conceive. He scourges with just contempt the assertions of mechanistic biologists that mind is a name for the physical and chemical actions of matter, since all the qualities which make matter anything else than ' pure being ' are conferred on it by mind.

Space is a general synopsis of our earliest fundamental experiences. Vision alone will not give us space, for the field of vision is spread out before the baby like a flat picture ; it is only gained when to this experience are added the efforts of the eye-muscles and of the arms in reaching after objects. This space which thus summarises our muscular experience is always three-dimensional Euclidean space,

and this is the only kind of space for which there is justification: all other so-called kinds of space are merely mathematical juggling with symbols.

Time, again, reflects the nature of our experience, which always consists of phases succeeding one another, and is irreversible; any other conception of time is merely a mathematical fiction.

Colour experience forms a scale of values beginning with deep red and passing through yellow, green, blue, and violet to something suspiciously like deep red again. Tone likewise exhibits a series of values in octaves; taste includes only four fundamentals. Sensations of odour, too, when properly investigated, will likewise reveal a similar scale of values. We live in a human world largely built up by our minds, and we can no more escape from it than we can lift ourselves up by our own waistbands.

In studying other living beings, therefore, and especially animals, we must always bear this limitation in mind. It is wrong, Uexküll asserts, to say there is one sun; there is a human sun, a lion's sun, and a fly's sun, as well as many others—and there is no certainty in correlating these with each other. But our earliest essays in comparative biology are completed when we are children: we then learn to distinguish some of the 'appearances' as our own body, from the outside world, because from the body we get a double set of stimuli—we can not only see it and feel it, but also sensations of pain arise in it when it is too roughly handled. When the crural nerves of a rat are severed it will devour its own toes—they are for it edible material and part of the outside world. Secondly, we learn to recognise amongst other 'appearances' some that are the envelopes of similar minds to our own. This is the really great advance in biology; all other subsequent advances are small in comparison to it. Zoology is merely the extension of this discovery so as to recognise behind another set of 'appearances' a series of minds in some respects resembling our own but much simpler, and in fact forming a graded series in degrees of simplicity.

Since our minds are awakened by stimuli received through the sense organs and express themselves in actions carried out by our muscles, we can hazard some kind of guess as to what the minds of animals must be like, in so far as we note a similarity between their sense organs and ours and a similarity between their effectors (muscles) and ours. As Uexküll expresses it: "Every animal is a subject which, thanks to its peculiar structure, selects from the general action of the outer world certain particular stimuli to which it responds. These responses consist in reciprocal actions on the outer world and these actions alter the stimuli: thus arises a circle which may be called the functional circle of the animal. The sum of the stimuli which act on the animal constitute a world; the stimuli shape themselves into objects (*Merkdinge*) which cause the animal to direct its motions, just as objects perceived at sea make the helmsman port his helm. The objects taken together may be termed the 'world of perception'. The conscious directive actions exercised by the animal on its movements form its 'inner world'. The movements themselves form a 'world of action'. The 'world of action' and the 'world of perception' taken together constitute the environment."

It is, of course, the aim of physiology to compare animals to machines and thus to explain as much of their actions as possible. This doctrine is heavily attacked by Uexküll. He points out that in every conceivable machine there are two elements, namely, the material out of which it is made and the framework of fixed parts by the reciprocal movements of which its movements are effected. So long as the framework is relatively rigid, the material out of which it is constructed is unimportant. But in the living organism there is no distinction between framework and material the two pass uninterruptedly into one another the living substance constructs the framework and can dissolve it. This is most strikingly shown by the simplest animals, such as *Amœba*, which may be justly said to be continually engaged in dissolving and then devouring their own framework. In the higher animals, every variety of framework muscular, nervous, glandular, and supporting takes its origin in similar cells made up of the same semi-fluid protoplasm as constitutes the body of *Amœba*. But the failure of the machine theory is most strikingly shown when we consider the development of the organism from the germ-cell.

As Uexküll shows with relentless logic, any mechanical theory of development, whether physical or chemical, necessarily involves an 'architecture of the germ-plasm', that is, a framework of different chemical substances in fixed relations to one another—a miniature replica of the framework of the body—and the discoveries of Driesch prove definitely and finally that such a framework does not exist.

Just as the deepest analysis of an animal's life leads to those 'conscious directive will impulses' which are ultimate and make up its

inner world' or psyche, so the study of development leads us back finally to a series of formative impulses succeeding one another, which Uexküll strangely confuses with the Mendelian 'genes'. The Mendelian 'genes' are simply names for aberrations or weakenings of the normal course of development. They are pathological in origin, as the recent work of Muller has proved, though it was fairly obvious from general considerations before. In the fresh-water shrimp *Gammarus*, on which Dr. E. J. Allen and Mrs. Sexton have carried out such thorough and painstaking investigations at Plymouth, there are no less than eight different kinds of germ-weakening or damage which will turn the normal black eye of the animal into a red one. But if we study the way in which the formative stimuli arise in a normal development which has been completely analysed, such as that of the sea-urchin, we find nothing remotely resembling Mendelian genes. The egg segments and gives rise to a ball of similar cells, and Driesch has proved that these cells are equipotential, each one of them having all the powers of the original cell, and if separated from its normal sisters and forced into a new position it is capable of producing any organ of the larva whatever. Then there comes a change: the protoplasm of one side of the ball can, by intucking, produce a gut—that of the other side cannot. Fresh potencies have been conferred on part of the protoplasm. The nuclei have not altered, all continue to possess the same number of chromosomes, but fresh emanations, most probably ferments, have been emitted into part of the protoplasm.

In later stages of development, Driesch has shown that at first any part of the gut will form a cœlomic vesicle, but that later this power is limited to the swollen tip, and if this tip be cut off, the truncated gut will heal but will produce nothing further. At a still later stage we ourselves have shown that a small segment of the cœlomic cavity known as the hydrocœle will act on the neighbouring skin so as to force it to produce the spines and tube-feet of the adult sea-urchin, and on the neighbouring mesoderm so as to compel it to produce the teeth and other ossicles of Aristotle's lantern. Thus the animal is built up, as Uexküll puts it, by a series of 'impulses' coming into action one after another which 'activate ferments' emitted from the nucleus.

If we examine more closely into the nature of these 'impulses', we find that each one of them is an imperfect repetition often repeated, in a word a blurred memory, of a former functional reaction of the organism to the environment, that is, a former *habit*, and so we discover that the impulses are memories of a series of habits superimposed one on another—a striking parallel on the corporeal side of the Freudian conception of the building up of the mind. It is to be regretted that Uexküll passes over almost completely the *historical* explanation of the structure and function of organisms which is embodied in the idea of evolution. No doubt he is led to this by his repulsion from the loose teleology implied in the Darwinian theory of natural selection. It is wrong, he says, to call one animal more perfectly adapted to its environment than another; the *Amœba* and the lion are equally well equipped to meet the calls which Nature makes on them: what is not well adapted belongs to the realm of pathology and not to biology (as incidentally do all mutations). When the environment changes, the animal within limits has the power of responding to the change, and the vigorous and healthy members of the species do so and pass on this power to their offspring; the 'random' variations in all directions, covertly assumed by Darwinism, simply do not exist.

It would far exceed the limits allowed by the most generous editor were we to attempt a full analysis of this wonderful book. No doubt each one of us who reads it will find something with which to disagree. We have indicated an important point where we are unable to see eye to eye with von Uexküll. We regret also very much that he still clings to the obsolete foam-work theory of protoplasm propounded by Bütschli, and that he accepts the crude theory of the purpose of 'eye' spots on the wings of peacock-butterflies as marks to deceive attacking birds. We have stood in a lane in Cornwall in August with a gorgeous array of admirals, peacocks, tortoiseshells, and other gaudy butterflies on the hedgerows on either side; the air was cleft with the arrow-like flight of low-flying swallows, and they molested the butterflies no more than we did.

Uexküll finds his deepest insight into the nature of life in the conception of *Planmässigkeit*, which we may perhaps translate as 'purposeful striving', and so it turns out that he has independently come to the very same conclusion as our comparative psychologist, William McDougall. Driesch's 'entelechy' is only another way of saying the same thing. Uexküll has earned the right to his opinion by a long series of brilliant researches in comparative physiology. It behoves all who desire to get a thorough insight into fundamental problems to study his book. E. W. MACBRIDE.

Chemistry and Monographs.

The Pyrolysis of Carbon Compounds. By Prof. C. D. Hurd. (American Chemical Society Monograph Series, No. 50.) Pp. 807. (New York: The Chemical Catalog Co., Inc., 1929.) 12.50 dollars.

THE serial scientific literature of the world increases yearly in bulk, and the knowledge contained therein is cumulative. Of all the sciences contributing to this already vast ocean of fact, theory, and opinion, chemistry, in all probability, heads the list, because the field covered by it and its related subjects is greater than that of any other science. The recent issue, in five volumes, of the decennial index of the American Chemical Society came as a startling reminder of what it is now thought proper to include under the head of pure and applied chemistry, and constituted a warning to which other societies, dealing with the publication of chemical abstracts, must have regard. It showed, moreover, that although reference to the original literature is essential to workers in connexion with their activities in some particular field, it cannot be regarded, except in special cases, as a practicable proposition for those who wish to keep abreast of development in sections other than those in which their own work lies. Views change, and much of the published work is subject to correction and alteration as the outcome of further research; a cause of confusion which is enhanced at the present time by the premature publication of results and conclusions by the 'young man in a hurry'.

In earlier days a systematic text-book provided all that was required, and lecturers were in a position to cover, with fair completeness, the whole field of chemistry as then known. But nowadays lectures have to be confined to the enunciation and description of principles, and it is no longer possible for even the most comprehensive of text-books to cover the field of any one of the great branches of chemical science. Recourse had thus to be made to other methods, and in the monograph a means has been found by which it is possible to treat special branches of chemistry in an adequate and reasonably up-to-date manner, which seems to provide a definite solution of the problem. Nevertheless, it is evident that, for any series of monographs to be effective, it must be wisely distributed among the subjects most likely to lead to an understanding of the science as a whole and must not be too specialised in character, and it is clear that this has been the aim before the special committee of the American Chemical Society, under the auspices of which the volume under review has been issued.

It was in July 1919 that the Inter-Allied Conference of Pure and Applied Chemistry deputed to the American Chemical Society the task of producing and publishing scientific and technological monographs on chemical subjects, and it is thus ten years since the Society took over this trust. In that period the Society has issued fifty volumes, which, as a perusal of the publisher's list shows, cover a wide area and embrace a large number of subjects related both to technology and pure science. This is a great record, and one which must be a source of gratification to the Committee and to the Chemical Catalog Company, which has acted as publishers. The book under review is the fiftieth of the series and constitutes a worthy jubilee volume.

At first sight it might be regarded as dangerous to deal with a subject such as organic chemistry from the point of view of some particular behaviour which the substances described show. Conditions of pyrolysis are difficult to determine. There are so many variables which are not subject to complete control: Surface action and the presence of catalysts; secondary chemical changes leading to the formation of products remotely different from those initially formed; products formed by the internal condensation of unstable reactants. These and many other considerations render the field one of the most difficult in modern research. Indeed, it does not appear as if full agreement has yet been reached regarding the behaviour of so simple a substance as methane when subjected to the action of heat. Nevertheless, it may be said at once that the author has succeeded in producing a very readable book, in which, by allocating organic compounds to groups, he has recorded published observations on their behaviour on pyrolysis which, for the first time, enable the reader to see at a glance some of the important changes organic substances undergo in this connexion.

It will probably be a surprise to many people to realise the important part played by pyrolysis in organic chemistry and the wide application it finds industrially. The cracking of petroleum is, for example, one of the most important industrial operations carried out at the present time, and constitutes the means by which much of the petrol required for our modern high-compression engines is produced. Again, the wandering of groups, especially those attached to nitrogen, affords the means by which many of our important dye-stuffs intermediates are manufactured. In the book

under review, organic substances are treated in the order in which they are usually found in organic chemistry text-books; compounds being chosen to illustrate the characteristic behaviour of substances of each group. Whenever any kind of generalisation is possible, it is brought clearly to light, but it is evident that much of the information is disjointed and does not admit of systemisation in the light of our present knowledge. Indeed, it is doubtful whether definite generalisation is possible in the great majority of cases, in the absence of any information regarding the action of catalysts or the surface action of the containing vessel.

Nevertheless, the manner in which the author has searched the literature for examples of pyrolytic change is remarkable, and the bibliography will be found of the greatest value. The book will undoubtedly be of great service to research workers and students, for whilst the method of treatment is unusual, it is none the less thorough and presents the subject from a point of view which has not been hitherto attempted. Like all books issued by the Chemical Catalog Co., it is well printed and the formulæ admirable. J. F. T.

School Physics.

(1) *Light: an Introductory Text-Book.* By C. G. Vernon. Pp. vii + 191 + 2 plates. (Cambridge: At the University Press, 1929.) 3*s.* 6*d.*; with Exercises, 4*s.*

(2) *Intermediate Heat.* By Dr. R. A. Houstoun. Pp. ix + 112. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1928.) 3*s.* 6*d.*

(3) *Heat, Light and Sound.* By P. J. Lancelot Smith. (Dent's Modern Science Series.) Pp. 368. (London and Toronto: J. M. Dent and Sons, Ltd., 1929.) 5*s.* 6*d.*

(4) *Energy.* By Sir Oliver Lodge. (Benn's Sixpenny Library, No. 65.) Pp. 79. (London: Ernest Benn, Ltd., 1929.) 6*d.*

THREE of these books are concerned to meet the demands of the First School Examination. With the examination system bulking so unduly in secondary education, the continued making of text-books with this aim is not to be wondered at. Years ahead we may decide otherwise the fate of the would-be science text-books in that day. We may ask: Is this book a distinctive contribution to teaching practice? Will it, in Sir Humphry Davy's words "add some little to the quantity of human knowledge, and of human happiness"? Will it lay the foundation for that appreciation of Nature and her ways on which the growing generation can build with success? Many text-books to-day could claim to pass the first question: how many school text-books could pass them all? For now we must content ourselves with the first question. Each of the following three books meets it with success.

(1) "Light" merits attention. It is a workmanlike attempt to develop an introductory course based on the concept of light as a wave motion, and is well worth the study of those science masters who confine themselves too closely to the old and unappetising course of thinly disguised geometry. Both methods should, of course, find a place in modern educational practice, but in what proportion is a problem for the individual physics master. Further, in the last chapter is a list of suggested experiments using the excellent apparatus of Mr. F. A. Meier of Rugby, described in the *School Science Review*, September 1922, in which "rays fixed by means of pins" are replaced by more illuminating beams. Mr. Vernon finds difficulty, however, in giving the history of his subject. Actually he summarises it in his first chapter. There the beginner meets "Newton's most famous experiment of course is the analysis of sunlight into a coloured spectrum using a prism", something of Snell and Descartes and the law of refraction, the disproof of the corpuscular theory, and so on. The interesting material here would have appeared much better incidentally, or more naturally in a concluding chapter.

(2) This deserves to be a very successful class book. It presents the essential facts concisely, and is developed logically. Many physics teachers must have wished for such a book, which does not rob them of their classical anecdotes or of all their illustrations, but serves as a sound framework for adding all those little things which give class teaching its value. Within the limits of about a hundred pages, Dr. Houstoun has done excellently.

(3) Here, too, is a good text-book. It covers a little more than is needed for matriculation, and is very suitable for work in the two years before that examination, where it is considered advisable to use one text-book only. If supplemented by a good practical course, it can be recommended as a safe and sound book. In dealing with reflection from spherical mirrors on p. 202, an unfortunate prominence is given to the generalisation: "Real images are always inverted". The limitation that this is true of real objects should have been emphasised.

(4) "Energy" should be the well-thumbed possession of every sixth form boy, even though he

is not on the science side. Its author's rare gifts of exposition and illustration are amply illustrated in this little book, which Messrs. Benn have done well to add to their excellent series. It has the distinction, won by all too few physics books, of passing successfully our third question posed above.

A. J. WHITE.

Our Bookshelf.

Éléments d'histologie. Par Prof. P. Bouin. Tome 1 : *Cellule ; division cellulaire ; différenciation cellulaire ; classification morphologique et fonctionnelle des cellules, tissus et organes ; éléments de soutien, contractiles, nutritifs ; sang, lymphe, organes hématopoiétiques, vaisseaux sanguins et lymphatiques.* Pp. vii + 334 + 2 planches. (Paris : Félix Alcan, 1929.) 120 francs.

ALTHOUGH the major part of organic histology remains to be treated in a second volume, and does not come within the scope of this present notice, it may be said that there is now no treatise of medical and general histology which does for English students what this work by the distinguished professor at Strasbourg does for the French. The appearance of the work is a restraining influence upon the increasing detachment of medical training from biological actualities and a check upon the facile conceptualism which makes precise knowledge of the organism a matter of professional indifference. The work is inspired throughout by that 'esprit biologique' which the author deems to be the foundation of medical science, while recognising that his specialty "can no longer limit itself to the study of the minute anatomy of the mammals, but should aim higher and further, concerning itself with some of the questions which preoccupy the minds of inquirers at the present moment".

If the work thus revives a diminished biological faith, it also affords general access to recent accumulations of knowledge, not merely as addenda but also in their proper perspective as parts of an orderly whole. There may be cited the sections dealing with protoplasm from a physico-chemical point of view, microdissection methods applied to karyokinesis; tactisms and tropisms; up-to-date articles on ossification, on joints, on the blood, the blood-vessels, and on the reticulo-endothelial system. Excellent bibliographies are provided to guide the student.

Text-books are, unfortunately, necessary. It is not the fault of any one in particular, but the inevitable fault of all, that they give undue publicity to error. W. Glaser, in pre-War days, figured "fine nerves passing close to a capillary, itself surrounded by somewhat thicker, spirally-arranged nerves". The figure reappeared in Müller's "Die Lebensnerven". Krogh borrowed it for his work on capillaries. It became famous, and many thousands of students have seen it on the lecture-screen. It appears in the present work over the description : "nervous terminations about a capillary, showing the spiral course of nerve fibrils". The vessel is not a true capillary, and the 'nerve' has the familiar features of the spiral muscular loops around small arteries. Although hundreds of investigators must have seen appearances identical with Glaser's photograph, his description —the sole evidence for the double innervation of capillaries—has not hitherto been questioned. The demand for objective verification of physiological theories is responsible for the spread of such legends, but not entirely for their authorship.

TUDOR JONES.

From the Seen to the Unseen. By the Rev. John H. Best. Pp. xii + 552. (London, New York and Toronto : Longmans, Green and Co., Ltd., 1929.) 18*s.* net.

THIS volume is an attempt to examine afresh the established facts and generalisations of modern science, and to ascertain how far such a consideration is capable of an interpretation in harmony with a belief in God as one who not only is absolutely good, but also is an active worker for the realisation of certain far-off beneficent ends.

The opening section of the book deals mainly with matters of a biological order. Mr. Best insists upon the failure to solve the details of embryonic development along the lines of pure mechanism, and in his psychological section he supports this view by pointing out how it would seem that the hypothesis of an inner principle of life is both desirable and necessary. Regarded from this point of view, the phenomena of life suggest to Mr. Best the existence of a supreme intelligence, and, arguing from similar premises, the theory is advanced that, in addition to intelligence and will, such human attributes as feeling and emotion may be added. Man's relation to the deity is then examined, and the conclusion is reached that, since the universe shows manifold indications of purpose in its later evolutionary stages, so the life of man suggests a purpose and a progress towards perfection.

Mr. Best's thesis is not new, but its freshness of treatment and sometimes originality of presentation may make it a valuable aid to those who, not content with a cautious agnosticism, prefer to seek support for their religious speculations in those departments of science which, from their very complexity, may not yet be sufficiently well understood to be described adequately in terms of the known.

The Annual of the British School at Athens. No. 28, Session 1926–1927. Pp. xi + 354 + 23 plates. (London : Macmillan and Co., Ltd., 1929.) 63*s.* net.

IN this volume we have a record of the operations of the British School of Archæology at Athens in the session 1926–27. In addition to the usual report of the Director and the accounts, it contains reports on the work which has been done by members of the School. The major operations continue to be the excavation at Sparta, where in the session of 1927 further work was carried out on the Theatre and the Acropolis. This is described by the Director, Prof. J. P. Droop contributing an

nalysis of the native pottery from the Acropolis nd Mr. W. Lamb a study of the bronzes from the Acropolis and the Orthia site. Mr. W. J. Forsdyke describes his excavation of the Mavro Spelio Cemetery at Knossos. These tombs were discovered n 1926, and the first five excavated by Sir Arthur Evans himself. From one of these came the gold ing with linear inscription described by him in the *Times* of June 8, 1927, in which he ascribed a alismanic meaning to the script. A paper of great nterest is that by Mr. W. A. Heurtley on the xcavation of a prehistoric site at Boubasta on the anks of the Haliakmon in Western Macedonia. The site, though small, was occupied over a very onsiderable period of time from the late Bronze Age. Not only is it interesting in itself as a hillside ettlement, probably of seasonal nomadic shepherds, but it affords Mr. Heurtley the basis for a omparative study of the painted pottery of northern Greece from which he makes some suggestive deductions as to a possible source for the Dorian nvasion.

Biology of the Vertebrates: a Comparative Study of Man and his Animal Allies. By Prof. Herbert Eugene Walter. Pp. xxv+788. (New York: The Macmillan Co., 1928.) 21*s.* net.

THE author states that his book is the outcome of wenty years' teaching of pre-medical students and thers, and in regard to the latter he says: "It s not so generally realised that it may not be miss for every man to gain some inside information about the human mechanism and how it ame to be." That is the keynote of the book. n the first part of the book taxonomy, distribution f animals in space and time, the ancient history f man, cytology, histology, and embryology are onsidered, and there is a short concluding section n biological discords. The second part deals with he skin, alimentary tract, and with the circulatory, espiratory, excretory, and reproductive systems, nd the third part with the skeleton, muscles, ervous system, and sense organs. In the second nd third parts is given an account—necessarily oncise—of the principal modifications of the rgan or system under consideration met with in he vertebrate series, and due reference is made to unctional activities.

To the student who has spent a year or so in oology and desires to proceed further in the study f the comparative biology of the vertebrates, this ook is a handy source of much interesting inormation which he would otherwise have difficulty in finding in small compass. Of the 687 textgures a few are on too small a scale to be really erviceable. Of errors there appear to be relatively ew, but *Xenopus* is not, as is stated, South merican.

ice Engineering. By Prof. Howard T. Barnes. Pp. vi+364+ii. (Montreal: Renouf Publishing Co., 1928.) 5 dollars.

TWENTY years ago, Prof. Barnes published his ork on "Ice Formation with Special Reference o Anchor Ice and Frazil", and in the lengthy bibliography contained at the end of his new work on ice engineering will be found many papers by him on various aspects of the ice problem. His life-long study of the blocking of the rivers of North America by ice and of the icebergs of the North Atlantic, led him to the discovery of the value of thermit for breaking up great masses of ice, and in 1925 he was granted a patent by the United States for his process. Thermit, it will be recalled, was discovered in 1895 by Dr. Hans Goldschmidt, who died in 1923. It is a mixture of aluminium powder and iron oxide which, when ignited, produces intense heat in a very short time. As applied by Prof. Barnes, thermit has been used for clearing the streams leading to power houses, for the prevention of floods, and for the breaking-up of icebergs, and only last winter the Canadian Government entered into a contract involving an expenditure of some £12,000 for an experiment on a large scale for the prevention of ice-jams on the St. Lawrence.

Details of some of the work done by Prof. Barnes is given in this volume, which, however, also deals with the physical properties of ice, the theory of the formation of anchor ice, ice remedial work, ice navigation, ice breaking, and other aspects of the subject. The bibliography is classified and chronological and contains references to papers by Boyle, Gay-Lussac, Faraday, Forbes, Kelvin, and other famous investigators.

Handbuch der regionalen Geologie. Herausgegeben von Prof. Dr. G. Steinmann und Prof. Dr. O. Wilckens. Band 7, Abteilung 7a: *The Union of South Africa.* By A. W. Rogers, A. L. Hall, P. A. Wagner and S. H. Haughton. Pp. 232+3 plates. (Heidelberg: Carl Winters Universitätsbuchhandlung, 1929.) 17 gold marks.

THESE 'handbooks' are indispensable works of reference for the countries they describe. The first part of the seventh volume deals with the Union of South Africa. The sections by the four main authors are supplemented by contributions by Dr. J. L. Krige, Dr. du Toit, and Prof. Shand. The book, as might be expected from the authors, deals mainly with the work of the Geological Survey, and includes a useful list of its maps and publications. The work is shorter than the volumes by du Toit and Krenkel, and its special value is as an authoritative statement of the present conclusions as to the classification and correlation of South African rocks. It may be noted that the Stormberg Series is all included in the Trias; the system in which the Ecca Series should be included is left indefinite; and the Waterberg System, from which the beds below the unconformity in it are excluded and referred to the Transvaal System, is accepted as pre-Palæozoic.

The section that is of particular value is the account of the complex and long series of rocks included in the pre-Palæozoic. The economic section by Dr. Wagner has an interesting account of the occurrence and distribution of the platinum ores.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts, intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Observations of the Total Eclipse of the Sun at Alor Star, Kedah, on May 9.

THE observations attempted by British observers at the total eclipse of the sun on May 9 were almost completely spoilt by cloud. At Alor Star in Kedah, the sky was covered throughout the day of the eclipse by high cloud through which the sun could generally be dimly seen. The prearranged programme was carried out, but the stars in the sun's neighbourhood did not show on the plates and the spectroscopic observations also failed.

Better success was obtained with the 6-inch lens of 45 feet focus which was used at Giggleswick, and the loan of which was extended by Mr. Worthington

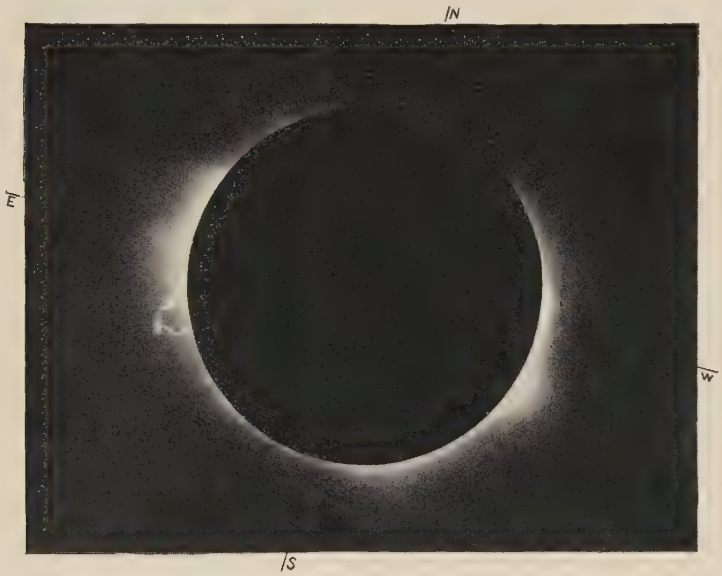

FIG. 1.

to this eclipse. The series of exposures from 3^s to 20^s were intended to show the prominences and the form of the inner corona. Although the longest exposure does not show more extension than was expected to be obtained from the shortest in a good sky, and although the longer exposures show a good deal of scattered light within the dark circle of the moon, the five plates give excellent pictures of the brighter details. The definition was excellent, such as it often is through cloud, and all the five plates show the same irregularities in the moon's limb. The reproduction (Fig. 1) is from the plate exposed from 200^s to 210^s after the beginning of totality. The filamentous prominence on the east limb is 180,000 miles long and 120,000 miles high—one of the largest ever photographed, though much inferior to that of 1919, especially in brilliance. The photographs taken near the beginning and end of totality show considerable differences in the structure of this prominence. On the western limb a beautiful coronal arch, besides much other detail, can be seen. The observers noted a considerable amount of red on this side of the eclipsed sun before the end of totality, but they did not see the large prominence on the eastern limb.

Small scale photographs were also secured through red filters. Those on kryptocyanine plates show the form of the corona best. The corona is of intermediate form and shows considerable difference from that generally obtained at sunspot maximum. On the panchromatic plates, also exposed through a red filter, the coronal extension is confused with the scattered light.

Photographic reproductions on paper 12 in. by 15 in., similar to those made from the photograph taken at Giggleswick, can be obtained from Mr. F. Jeffries, Royal Observatory, Greenwich, price 2*s.* 6*d.* each.

A Possible Origin of Faint Fraunhofer Lines.

THERE are about 20,000 lines in the Fraunhofer spectrum of the sun (excluding the infra-red part), of which only about 6000 have been correctly identified with the lines of known elements, and with the lines of certain band spectra (cyanogen, Swan, etc.). The origin of the others is still wrapped in mystery. Possibly a large number may be found to coincide with the fainter lines of complicated spectra of elements like iron, nickel, etc., particularly with those belonging to higher Rydberg sequences. For some time past we have been thinking of a third possibility of the origin of these lines, namely, whether a large number may not be ascribed to the combined effect of Raman scattering and ordinary absorption. For example, molecules which are responsible for the emission of the cyanogen and Swan bands are strongly present in the sun, and when a beam of light falls on them from the photosphere, this light may be supposed to be modified by Raman scattering to the frequency $\nu - \nu'$, where ν' is some frequency corresponding to a strong vibration-rotation frequency of the CN-molecule. If $\nu - \nu'$ happens now to coincide with the H or the K frequency, the modified light will be absorbed by the high level Ca^+-atoms, and we shall get an absorption line in the place of the original frequency ν.

Taking the strong vibrational-rotational frequencies of the CN-molecule (particularly those which are expected to be strong at the solar temperature), I have calculated the lines which, after being modified by Raman scattering, are absorbed by the Ca^+-atoms. I have obtained lines which agree very closely with Fraunhofer lines of intensity $(-3, -2, -1)$ for both H- and K-lines. Some calculated lines coincide with the recorded faint lines of other elements. But even leaving these aside, the evidence obtained is strongly in favour of the view presented in this note. If we calculate the lines modified by such molecules as H_2, which are known not to occur in the solar spectrum, the coincidences are found to be either entirely lacking or rather poor.

Of course, in the circumstances, it is impossible to get absolute confirmation of the view, but probably a plausible case has been made out that Raman scattering may be responsible for the origin of a large number of faint Fraunhofer lines. If the view be correct, it will afford us a method for calculating the total number

f molecules of CN in the solar atmosphere from a omparison of the intensities of the modified line with hat of the K-lines, with the aid of known dispersion ormulæ.

It may be mentioned that this investigation was riginally undertaken with the view of finding out whether some of the lines of the coronal spectrum may ot be due to Raman scattering of strong Fraunhofer nes by molecules on the sun. Though certain triking coincidences were obtained, for example, the requency of the green coronal line λ5303 comes out to e equal to $\nu - \nu'$, ν = frequency of the K-line, ν' is a trong vibrational-rotational frequency of the H_2-nolecule, the corresponding modified frequency for he H-line was found to be absent, and hence the view vas abandoned. It does not appear that the coronal pectrum is due to modification of strong Fraunhofer nes by Raman scattering.

My best thanks are due to Prof. M. N. Saha for indly suggesting the problem and for his continual uidance.

Fine Structure in the Helium Band Lines.

As is now well known, the electron levels of He_2 all into two systems, p-He_2 and o-He_2, paralleling the -He and o-He terms. The o-He_2 and p-He_2 levels e, on theoretical grounds, probably respectively triplets and singlets like the corresponding atomic levels (cf. especially W. Weizel, *Zeits. f. Physik*, **51**, 328; **52**, 175; **54**, 321; 1928–29). But no evidence of triplet structure in the o-He_2 levels has been reported, except probably in one perturbed 5π rotational level (cf. G. H. Dieke, Nature, Mar. 23, 1929). This is not altogether surprising, since the o-He terms show only very narrow fine structures, the largest separations being in the $2\,^3P$ term ($^3P_0 - {}^3P_1$, $\Delta\nu = 0{\cdot}991$, $^3P_1 - {}^3P_2$, $\Delta\nu = 0{\cdot}077$).

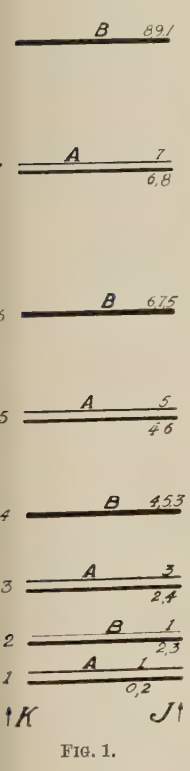

Fig. 1.

On photographing the He_2 bands with somewhat higher resolving power than hitherto, we have found fine structure in the lines of a number of o-He_2 bands having $2\,^3\pi$ as their lower electronic state. On the other hand, the $2\,^3\Sigma - 3\,^3\pi$ band λ4650 shows no evidence of fine structure.

The bands λ6400 ($2\,^3\pi - 3\,^3\Sigma$), λ4546 ($2\,^3\pi - 4\,^3\Sigma$), and λ5733 ($2\,^3\pi - 3\,^3\Delta$) all show qualitatively the same fine structure for all band lines which end on any given rotational level, but the quantitative separations appear to be smaller in some of the λ5733 lines. Other bands ($2\,^3\pi - 3\,^3\chi$ and $2\,^3\pi - 4\,^3\chi$) show similar relations.

We conclude that the observed band-line patterns re mainly determined by the fine structures of the otational levels of the $2\,^3\pi$ state, and that the fine tructures of the other states involved are smaller $^3\chi$, $3\,^3\Delta$) or negligible (probably, $^3\Sigma$ states). The ccompanying diagram (Fig. 1) shows the lower otational levels of the $2\,^3\pi$ state, correctly spaced, ut with the fine structures exaggerated twenty-five-old. The fine structures shown are drawn the same as those observed for the λ6400 band lines. The doublet separations, as measured for successive A levels, diminish slowly from $\Delta\nu = 0{\cdot}34$ for the lowest level, but the intensity ratio (about 2 : 1 in favour of the high-frequency component) appears to be constant. For the lowest B level, $\Delta\nu = 0{\cdot}25$, with the long-wave component very weak, while succeeding levels are merely broadened.

The $2\,^3\pi$ fine structures may be interpreted as follows. If K is the rotational quantum number when the spin S is neglected, one expects for triplets ($S = 1$) a fine structure with three levels ($J = K$, $K \pm 1$), each having a statistical weight $2J + 1$. Suppose, for given K, the levels with $J = K \pm 1$ approximately fall together, while $J = K$ is distinct; the composite $J = K \pm 1$ then has twice the weight of the level $J = K$. This supposition explains well the observed relations in the A class of rotational levels. (This fine structure type is apparently similar to that observed in the $^3\Sigma$ normal state of O_2; cf. Mulliken, *Phys. Rev.*, **32**, 880; 1928: Kramers, *Zeits. f. Physik*, **53**, 422; 1929.) To explain the B level fine structures we may assume that $J = K$ and $J = K + 1$ approximately fall together for $K = 2$, while $J = K - 1$ lies higher; but that for $K = 4$, 6, . . . the three levels $J = K$, $K \pm 1$ are only sufficiently separated to give a broadening without resolved fine structure. The assumption made for $K = 2$ would give a 4 : 1 intensity ratio for the members of the observed doublet, in harmony with the estimated experimental ratio.

The Zeeman effect of these He_2 bands is also of interest. In a field of 30,000 gauss the Q (1) line of the λ6400 band becomes in parallel polarisation a doublet of width $\Delta\nu_n$, in perpendicular polarisation a corresponding triplet, the components being very sharp in each case. The unresolved patterns of the higher Q lines in parallel polarisation, and of the P and R lines in perpendicular polarisation, appear as doublets. The results are exactly what theory predicts for singlet levels (cf. Curtis and Jevons, *Proc. Roy. Soc.*, A, **120**, 110; 1928). The original fine structure is evidently wiped out here by a Paschen-Back effect.

Further details will be given elsewhere.

Use of the Thermionic Valve in Measurements of Ionisation Currents.

Owing to the extremely high humidity of the atmosphere in many parts of the east, the use of the quadrant electrometer for the measurement of ionisation currents is limited to a few months in the dry season. Recently we had occasion to demonstrate some of the ordinary experiments on the properties of ionisation currents, and found the following device quite satisfactory. In Fig. 1, AB is an ordinary ionisation chamber of which the upper plate A is connected to a battery of cells B_2, the lower plate B, on which is spread uranium oxide, being connected to earth through a high resistance R. This high resistance is inserted in the grid circuit of the valve V (Mullard type I.H.F.). Initially, with the key K open, the anode current is compensated by the potential balancing device Z, so that the galvanometer indicates zero. On closing the key the ionisation current flows through R, the grid potential is altered and the galvanometer is deflected. Varying the voltage on A, the ordinary increase of ionisation current up to saturation can thus be recorded.

The resistance R consists of a mixture of xylol and alcohol (10 : 1) contained in a sealed quill tube 20 cm. long. It had a resistance of approximately 10^{11} ohms as determined by the leakage method. Z would be, perhaps, 4000 ohms.

Experiments are now in progress to test the application of this method to the absolute measurement of ionisation currents. With a resistance of 10^{11} ohms a current of 10^{-12} amp. should produce a voltage on the grid of 10^{-1} volt, and hence an alteration of anode current for the type of valve used of about 20 microamp., which could be recorded on an

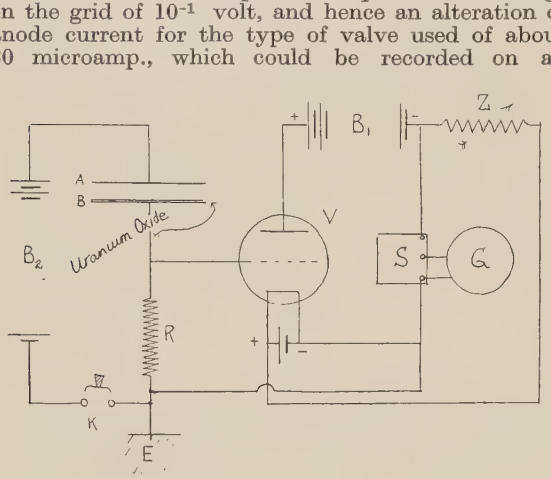

FIG. 1.

ordinary unipivot galvanometer. Still smaller ionisation current should be measurable with equal accuracy by employing still higher resistances. Whilst responding to the ionisation produced by X-rays, this method is unsuitable owing to the extreme sensitivity of the valve to high frequency disturbances. It is possible, however, that this difficulty may be overcome by careful screening. Unsteadiness due to capacity effects is very much minimised by operating the key from a distance. The possibilities of this method are now being investigated, and it is hoped to publish the full details in the near future.

I am much indebted to Mr. N. G. Srinivasan, who made the high resistances used and assisted me in setting up and carrying out the experiments.

A Relation between Raman Spectra and Ultra-Violet Absorption.

IT is well known that the Raman frequencies are identified with vibration frequencies of the molecule, and this is corroborated by the agreement already found between Raman lines and absorption bands in the infra-red. It is to be anticipated, however, that a polyatomic organic molecule with its several frequencies of vibration would give a rather complicated absorption spectrum, so that the dispersion of the spectroscope in the infra-red is often insufficient for their resolution. The result is therefore a superposition of bands on a continuous background, the maxima of which may correspond to average values between two or more bands. In fact, the agreement between Raman spectra and infra-red absorption is in many cases not quite satisfying.

For the ultra-violet absorption spectrum of vapours the experimental conditions are better. Many organic substances yield absorption spectra consisting of well-resolved bands, and with the high dispersion available in this region, these can be measured with great accuracy.

Following up a suggestion made by Prof. V. Henri that the Raman spectra give the possibility of determining the vibrational frequencies of the normal state, a comparison was made of the ultra-violet absorption and Raman spectra of several compounds.

Chlorbenzol shows this relationship very clearly and was therefore chosen for a more complete study. The absorption spectrum of chlorbenzol vapour consists of numerous bands and lines (about 350 measured) extending from 2780 A. to 2250 A. Under the assumption that the strongest band in the spectrum is due to the electronic transition from the lowest level in the normal state to the lowest level in the excited state, a general analysis of the spectrum is possible by means of the Raman frequencies. From this band, $\nu_0 = 37052{\cdot}9$ cm.$^{-1}$; in the direction of longer wave-lengths there are a number of weaker bands at frequencies agreeing with the Raman frequencies. In the same way, going out from strong bands farther in the ultra-violet, which correspond to higher vibrational states of the excited molecule, similar weak bands are to be found toward longer wave-lengths, which again show separations equal to the Raman frequencies.

The frequencies measured in this way in the ultra-violet spectrum, compared with the Raman frequencies (in parenthesis), as measured in this laboratory are, in cm.$^{-1}$: 201·9 (196), 242·1 (242), 418·9 (420), 618·6 (618), 622·9 (618), 707·9 (706), 822·7 (823), 1004·8 (1005), 1024·6 (1025), 1087·1 (1088), 1157·2 (1162), 1585·0 (1583), 3063·3 (3064). The analysis of the spectrum shows that the strongest frequencies of vibration in the excited state are : 318·8, 519·0, 523·9, 929·8, and 962·6 cm.$^{-1}$.

The level corresponding to the Raman line 618 cm.$^{-1}$ is found to be double in the ultra-violet absorption, and the corresponding level in the excited state is also double. As the separation of these doublet levels increases proportionally with the quantum number, it is possible that an isotope effect due to the chlorine atom is the factor responsible for the doubling.

The complete analysis of the ultra-violet absorption spectrum of chlorbenzol will appear shortly elsewhere.

Raman Effect in Carbon Dioxide.

IN NATURE of Feb. 9, F. Rasetti has published his observations on the Raman effect in carbon dioxide. He has found the lines at λ4639, λ4616 and λ4289, λ4268, excited respectively by the mercury lines at λ4358·343 and λ4046·560. These modified lines are due to the following transitions :

λ.	ν.		ν.	μ.	μ.
4358·343	22943·35	Diff.	1285·62	7·776	7·788
4616·000	21657·73				
4046·560	24705·40	Diff.	1281·80	7·799	
4268·000	23423·60				
4358·343	22843·35	Diff.	1393·00	7·177	7·168
4639·000	21550·35				
4046·560	24705·40	Diff.	1396·48	7·159	
4289·000	23308·92				

The lines thus correspond to an absorption band near about the region 7·8 μ, having for its components the radiations due to 7·788 μ and 7·168 μ. These components may be due to changes in the vibrational

states, one to a transition from state 0 to state 1, the other from state 1 to state 0. Both these states may be expected to occur under ordinary conditions when the moment of inertia of the molecule is large, as in the case of carbon dioxide.

These modified lines show that the model of carbon dioxide is a linear one as considered by Eucken (*Zeits. f. Physik*, **37**, 714; 1926), who has calculated the frequency corresponding to the vibration along the direction joining the C- and O-atoms to be of that of an anharmonic oscillator having a frequency corresponding to 7·86 μ—this frequency being optically inactive in the case of absorption. In the case of scattering, this frequency will evidently be the one which will be the most prominent. Of the other two fundamentals at 4·25 μ and 14·87 μ, one may be optically inactive in the case of scattering, and the intensity contribution of the other may be so feeble that it would require a very large exposure to show its presence. It may here be pointed out that the pair of bands at 2·7 μ, which has been considered as a fundamental by Schaefer and Phillipps, has been shown by Eucken as due to combination frequencies, and one is not justified in considering it as a fundamental due to its weak intensity. That the carbon dioxide molecule has a linear model is also shown by the absence of a permanent dipole moment and from the ordinary scattering data.

Thus the observations of Rasetti are a very clear proof not only of the Raman effect, but also of the linear model of carbon dioxide. It is also expected that in the other triatomic molecules where the dielectric constant data show the absence of a permanent dipole moment due to linear structure with symmetrical disposition of the two atoms on each side of the central one, the Raman effect would be shown evidently with less exposure for the optically inactive fundamental frequency in absorption.

Further Investigation on Incoherent Scattering in Gases.

IN letters to NATURE, and in two papers published in the *Proc. Nat. Acad. Sci.* of America, I have reported some results obtained on the Raman effect in gases. I want to report now about some new experiments, which will be more completely described in the *Physical Review*.

I have observed, for the first time, so far as I know, a purely electronic transition in the scattering process. The molecule NO has a normal ^2P state, the separation of the doublet being about 124 cm.$^{-1}$; the two levels arise from the two opposite orientations of the electronic spin relatively to i_1, that is, to the nuclear axis. I have found this transition in the Raman spectrum excited by λ2536.

I have built a new apparatus in order to work with gases at 10 atmospheres pressure, with ultra-violet excitation. In this way I have obtained beautiful Raman spectra of hydrogen. They show eight lines corresponding to purely rotational transitions, and also well-developed vibrational-rotational Raman bands, of which so far only unresolved Q-form branches had been recorded. I have measured now three lines of the Q-form branch, four of the RR-form branch, and one of the PP-form branch for the transition from the zero to the first vibrational level.

From this, not only the moment of inertia and the vibration frequency of the H_2 molecule can be calculated with high accuracy, but also the coupling between rotation and vibration.

Gaseous hydrocarbons at ten atmospheres give strong Raman lines in a few hours' exposure. Systematic work is being extended in this direction.

Statistics in Biological Research.

IN the review of Dr. R. A. Fisher's "Statistical Methods for Research Workers" in NATURE of June 8, the point is made that a careless reader may get the impression that the various methods outlined therein will give exact results when applied to the ordinary small 'sample', although we have, in general, no proof, or even expectation, that the sample is drawn from a 'normal' population, to which alone the tables can be exactly applied. That this is so is clear from the fact that an American writer has stated that the English school of statisticians claims to have produced tables which may be used for samples, however small, drawn from any conceivable population; but of course Dr. Fisher would be the first to cry out against the foolishness of making any such claim.

That such a misconception should arise is perhaps not unnatural when a mathematician is trying to explain what he has been doing to those who lack the mathematical outlook, but this would presumably not apply to the reviewer; yet by his use of the word 'admit' when doubtless he meant 'stress' ("It would seem wiser . . . to admit the incompleteness of theory . . .") he runs the risk of seeming to support a misstatement which Dr. Fisher may well resent.

The question of the applicability of normal theory to non-normal material is, however, of considerable importance and merits attention both from the mathematician and from those of us whose province it is to apply the results of his labours to practical work. Personally, I have always believed, without perhaps any very definite grounds for this belief, that in point of fact 'Student's' distribution will be found to be very little affected by the sort of small departures from normality which obtain in most biological and experimental work, and recent work on small samples confirms me in this belief. We should all of us, however, be grateful to Dr. Fisher if he would show us elsewhere on theoretical grounds what *sort* of modification of his tables we require to make when the samples with which we are working are drawn from populations which are neither symmetrical nor mesokurtic.

The Long Period Variations of UZ Persei.

IN *Harvard College Observatory Bulletin*, No. 867, Feb. 1, 1929, there is a note by B. P. Gerasimovič on "UZ Persei, a Variable of Unusually Long Period". The author found that the brightness of this variable star has two oscillations—short and long—with periods of about 90 and 907 days respectively. It is known that such oscillations are typical for μ Cephei.

In a short note (*Astronomical Bulletin*, Mirowedenije, Nr. 22, 1928) I showed from 3785 observations that μ Cephei has three oscillations. The periods of these oscillations are 90 days, 600 days and 13 years. The most interesting is the last oscillation, on account

of its long period and distinctly observed amplitude 0·5 st. mag.

It was interesting to look for this long period in the case of UZ Persei. Indeed, Mr. Gerasimovič's light-curve shows that the brightness at minima and maxima does not remain constant, but varies slowly.

It may be seen from the accompanying table that

Minimum I.D.	mag.	Maximum I.D.	mag.
2,417,450	10·85	2,416,800	10·56
8,300	10·90	7,800	10·55
9,200	11·00	8,700	10·62
2,420,200	10·88	9,700	10·57
1,100	10·72	2,420,800	10·45
2,000	10·75	1,550	10·48
..	..	2,400	10·52
Range	10·72-11·00	Range	10·45-10·62

there is a secular oscillation with a long period of about 5000 days or 14 years, and amplitude 0·3 mag.

It is clear that this star is of μ Cephei type. My paper on μ Cephei and the principle of classification of irregular variable stars of this type will be published later. W. ZESSEWITSCH.

University Observatory,
Leningrad, May 18.

Rapid Approximate Calculation.

FOR all work in which an error up to 10 per cent in the final result is admissible, the following rough logarithm-table provides a means of multiplying and dividing which is appreciably more rapid than direct calculation, and in simple cases does not require pencil and paper.

Log..	0·1	0·2	0·3	0·4	0·5	0·6	0·7	0·8	0·9
No. .	5/4	$\pi/2$	2	5/2	π	4	5	2π	8

With some of the figures, of course, everyone who has occasion to use logarithms at all is familiar; that the logarithms of $\pi/2$ and 2π can be obtained from that of π by subtracting or adding 0·3 is also in itself self-evident; nevertheless, it seems worth while to point out explicitly how very convenient it is to be absolutely familiar with the whole table. The error in every case is less than 1 per cent, and with a little practice it will be found possible also to estimate very quickly the second place of decimals for any number at all, with an error that is usually less than 1. An error of 4 in the second place, corresponding to 10 per cent in the number, should then occur only in the results of fairly complicated calculations.

An error in the decimal point is much less probable than when working with the slide-rule; the method is in fact very reliable for fixing the position of the decimal point in slide-rule results. Its principal other applications are obviously for estimating whether a theory or an experimental method is roughly suitable for a particular purpose, and for checking the experimental results of students in cases where a numerical slip is suspected.

Berlin, May 29.

The Spectrum of the Corona.

IN view of the interest attaching to the identification of the unknown lines of the solar corona, I have examined the possibility that they might be due to the occurrence of 'forbidden' transitions between terms in the spectra of ionised iron (Fe II), calcium (Ca II), titanium (Ti II, Ti III) and argon (Ar II), as well as several important forbidden transitions of the neutral titanium atom.

Ionised iron, calcium and titanium are all present at high levels in the chromosphere, and although there is no indication that argon is present, it was examined in consequence of a suggestion, now disproved by H. N. Russell and I. S. Bowen (*Astrophysical Journal*, **69**, 196; 1929), that the coronal lines might arise from neutral argon. Wave-lengths corresponding to some 500 forbidden transitions have been computed, but in no case have any coincidences been found between these and the coronal wave-lengths which would not be considered a pure matter of chance. Similar calculations seem to have been made by I. S. Bowen and D. H. Menzell (*Publ. Astro. Soc. Pac.*, **40**, 322; 1928), but details of this publication have not been available to me.

Another possibility that the coronal lines might arise in second type collisions involving the metastable 1δ terms of ionised calcium (Ca II) is under consideration, but has so far also yielded negative results. E. M. LINDSAY.

The Ovarian Hormones.

THE writer of an article on "The Hormones of the Sexual Glands" in NATURE of June 15, p. 913, says that "the œstrous reaction of ovariectomised animals following an injection of 'œstrin' appears incomplete, in that copulation is only infrequently observed, and in the spayed bitch the hormone only produces symptoms of pro-œstrus, so that possibly the missing factor may be the hormone responsible for the initial development of the accessory sex organs". The reference is probably to a paper by Dr. S. A. Asdell and myself published in the *Proceedings of the Royal Society* (1927), but it is to be pointed out that the injections described in that paper were made into anœstrous bitches and not into spayed ones. The argument above quoted, therefore, does not apply. I write open to correction and without the references before me, but I believe I am right in saying that Dr. Wiesner of Edinburgh has concluded from experimental evidence that more than one ovarian factor is concerned in the production of pro-œstrum and œstrus. F. H. A. MARSHALL.

Beresford, Yarmouth,
Isle of Wight,
June 21.

THE paragraph to which Dr. Marshall refers was based on two statements made by Parkes in his review of ovarian activity (*Biol. Reviews*, vol. 3, pp. 212 and 213; 1928), quoting papers by Parkes, Fielding and Brambell (*Proc. Roy. Soc.*, vol. 101; 1927) and by Asdell and Marshall, the paper to which Dr. Marshall refers. Parkes found that of 92 induced œstrous periods in ovariectomised mice kept with males, only 7 were accompanied by copulation; of these 7, 3 occurred in mice which were found to have regenerated ovarian tissue. I had not referred to the original papers when writing the article and accept Dr. Marshall's correction. On the other hand, the failure of the injections in Dr. Marshall's experiment to provoke the full œstrous reaction surely indicates that a further factor is required, unless it is assumed that some inhibiting factor is present in the anœstrous bitch. THE WRITER OF THE ARTICLE.

Mineral Metabolism: Iodine and Sulphur.

THE importance of the mineral salts in nutrition is sometimes obscured by the greater attention devoted to other dietary constituents, more especially within recent years to the vitamins; but, of course, they are just as important for life as any of the other irreplaceable elements of the diet. The functions of the chlorides of sodium, potassium, and calcium in maintaining the osmotic equilibria between the fluids and cells of the body, without which the latter cannot function normally, the necessity of a supply of calcium and phosphorus for the formation of bone, and of iodine for the production of thyroxine, and the part played by the sulphur-containing amino-acid, cystine, in growth, all indicate the importance of studies of the mineral metabolism.

The functions of iodine and sulphur in the animal economy offer some interesting analogies as well as points of contrast, and have recently been reviewed by Orr and Leitch,[1] and Marston and Brailsford Robertson,[2] respectively. Our knowledge of the metabolism of these two elements, although extensive, is still incomplete at many points, but critical reviews are of value by indicating both the present position of our knowledge and also the points at which further work may be at the moment most profitably carried on. The present article will summarise briefly some of the more salient features of the positions of iodine and sulphur in nutrition and metabolism.

Iodine.

It is of interest to note that the work of the first quarter of the twentieth century has been largely a repetition of that carried out during the first half of the nineteenth, with the result that the earlier conclusions have been essentially confirmed, although the investigations were performed with few of the modern facilities for accurate research work which we now possess.

Iodine is very widely distributed in Nature, but it is usually present in only minute amounts. Even in its richest sources, such as saltpetre deposits and sponges, its maximum concentration does not exceed 0·1-0·2 per cent. In other minerals or animal tissues the amount present may be reckoned in thousandths of a milligram. It has been found in all geological deposits examined in concentrations varying from 170 γ to 9200 γ per kgm. ($\gamma = 10^{-6}$ gm.); in soils it occurs in quantities varying from 600 γ to 6000 γ per kgm.; it tends to be absorbed by acid soils and is concentrated by the plants growing on the soil, both processes leading to enrichment of the soil. On the other hand, depletion occurs in basic soils or those rich in calcium and also in heavily cropped soils. Water contains much less iodine than soil; fresh, 1 γ per litre, and salt, 17-18 γ per litre; marine plants and seaweed concentrate the iodine from sea water and form rich sources of the element. Only traces are found in salt deposits or in air.

It thus appears that plants must provide the main source of iodine for animals, and it is of importance to know something of the factors affecting the iodine content of the former. The available iodine in the soil, which may not be the same as the total iodine, is of much greater importance in determining the iodine content than the species to which the plant belongs; but the actual part of the plant in which the concentration is highest varies with the species. Sea plants contain the most iodine and land plants the least, with freshwater intermediate. The effects of supplying additional iodine for plant assimilation depend on the dosage used, the species of plant, and the medium to which it is added. In general, it may be stated that with the amount of iodine available at its optimum level, growth is at its maximum, and the iodine concentration and nitrogen assimilation are increased; the storage of useful products, for example, sugar in the sugar-beet, is improved, and there is also an increase in the aerobic respiration, and in the *p*H of the cell sap; the activity of nitrifying bacteria is stimulated. Doses greater than the optimum are toxic, but the amount required to produce such an effect varies with the species of plant studied.

In animals, the iodine content of the thyroid gland reaches 0·1-0·2 per cent or more of the dry weight, but the concentration in the other tissues of the body is much less. At present the only known function of iodine in the animal economy is in the formation of thyroxine, a stimulator of metabolism and essential for growth and health. In addition to thyroxine, the thyroid gland also contains di-iodo-tyrosine, and it appears probable that these two compounds account for the whole of the iodine content of the gland (C. R. Harington and S. S. Randall: *Chem. and Indust.*, vol. 48, p. 296; 1929). The latter is influenced by a number of factors, but depends chiefly on the intake of iodine and less upon the age, sex, or species. The differences between individuals of the same species are as wide as any differences between species, except that the glands of sea fish contain up to 1·6 per cent iodine (dry weight), whilst those of rats appear to have a low content, 0·06 per cent (dry weight) having been reported, but these differences are probably explicable by varying levels of intake. In normal glands the total iodine content increases with the age of the individual as the gland grows to its maximum in adult life, the iodine percentage remaining fairly constant; only in the very young fœtus is the percentage lower. In some animals the iodine content is greatest in autumn, coincident with an increase in the iodine content of the pasture; the percentage also varies inversely with the

[1] Medical Research Council. Special Report Series, No. 123: Iodine in Nutrition; a Review of Existing Information. By J. B. Orr and I. Leitch. Pp. 108. (London: H.M. Stationery Office, 1929.) 2*s*. 6*d*. net.

weight of the gland, but this is only true of normal glands.

The concentration of iodine in other tissues is low, for example, 5-15 γ per 100 c.c. of blood, rising in women at the beginning of menstruation, doubtless due to change in the physiological activity of the thyroid gland with the sexual cycle. The body tissues generally account for 40-80 per cent of the total iodine, according to the species, the remainder being in the thyroid gland.

The effects of the administration of iodine to animals are in many ways similar to those produced by feeding thyroid gland itself, since the iodine may modify the gland's secretion. Both inorganic and organic iodine occur in the blood; the former is passing to the gland or results from the disintegration of thyroxine in the cells of the body. The latter is probably chiefly thyroxine itself, on passage to the tissues of the body, since its amount is decreased after thyroidectomy. It may be pointed out here that inorganic iodine can be readily assimilated by the body, whereas inorganic sulphur cannot be utilised, only organic compounds of the latter being taken up and metabolised.

Iodine may produce increased growth in animals and in children in goitrous areas, but such a result appears to be presumptive evidence that the intake was previously below the optimum. On the other hand, thyroid administered in excess can inhibit growth, acting as a toxic agent. Small doses of iodine or thyroid increase the retention of nitrogen, whilst the larger doses of the latter increase its output; coincident with these effects, thyroid administration stimulates the general metabolic processes of the whole body, whilst small doses of iodine may, under certain conditions, decrease these, at the same time decreasing the organic iodine in the blood.

Light has been thrown on the physiology of the thyroid gland by studies of its diseases. A healthy gland stores colloid in its acini, but this only occurs where the iodine content is about 0·1 per cent of the dry weight, or 0·03 per cent of the fresh weight or more; hence an adequate intake of iodine is essential for the proper functioning of the gland. In both simple and exophthalmic goitre the percentage of iodine is subnormal. The variations in the supply of thyroxine to the tissues are reflected in alterations in the concentration of iodine in the blood.

Data from metabolism experiments and the average iodine intake in non-goitre as compared with goitre areas indicate that the minimum daily amount required for equilibrium is, in the adult, 15 γ, and in the child, 50 γ, but to allow a liberal margin of safety, at least three times these quantities should be consumed. Endemic goitre can be prevented and usually cured by supplementing the iodine intake, and it has been found that about 100 γ daily are required; this amount can be conveniently obtained by using salt to which a small dose (1 : 200,000) of potassium iodide has been added.

To sum up, animals can obtain the iodine they require from such a source as an inorganic iodide, or iodine itself may be administered; usually the requisite quantity is consumed with the animal or vegetable food eaten, partly in inorganic and also probably partly in organic form, but little is known of the organic iodine compounds in plants. In animals the iodine is taken up by the thyroid gland, for the formation of thyroxine, di-iodo-tyrosine presumably being an intermediate stage. The thyroxine has a profound influence upon the metabolism of all the cells of the body; although after its administration in even a small dose, the stimulating effect is prolonged, yet the continual loss of iodine from the body indicates that the thyroxine is continually destroyed, with the result that a steady supply of iodine is necessary to maintain a constant formation of the hormone. In the absence of a sufficient absorption of this element, the thyroid gland enlarges, and finally may fail to supply sufficient thyroxine for the needs of the body, producing a slowing of metabolism in the adult, and also, in the young, failure of growth.

Sulphur.

In contrast to iodine, animals can only utilise organic sulphur, inorganic forms being treated as waste products and excreted. Hence they are dependent upon plants or other animals for their supply of this essential element. Plants, however, can utilise sulphur and sulphates, and their addition to soils poor in sulphur increases not only the content of this element, but also the assimilation of nitrogen, indicating presumably the formation of sulphur-containing amino-acids.

Until recently, only one organic compound containing sulphur was known which is assimilable by animals, the amino-acid cystine. Natural cystine is lævo-rotatory and differs in its properties from its optical isomer and the racemic form. The cystine content of proteins, both vegetable and animal, is usually low, varying from 0·5 to 3·0 per cent, but it is still lower in gelatin and casein; wool keratin, however, contains about 13 per cent, and the protein from *Antiaris toxicaria* upwards of 25 per cent. Part of the sulphur in proteins can be split off as hydrogen sulphide by heating with alkali, suggesting that two forms of sulphur exist in the molecule, and therefore that cystine is not the only sulphur-containing amino-acid present. More recent work, however, has demonstrated that sulphur in diketo-piperazine linkage is very labile to alkali, and the two forms of sulphur disclosed by this reagent in the molecule may simply indicate cystine in diketo-piperazine and in catenary linkage respectively.

A second sulphur-containing amino-acid has been isolated from caseinogen and some other proteins in amounts of less than one-half per cent, and Barger and Coyne have recently succeeded in synthesising it and determining its constitution; it is γ-methyl thiol-α-amino-butyric acid, $CH_3 . S . CH_2 . CH_2 . CH(NH_2) . COOH$, and has been called 'methionine' (G. Barger and F. P. Coyne, *Biochem. Jour.*, vol. 22, p. 1417; 1928). The

starting-point in the synthesis was β-methylthiol-propaldehydeacetal formed from methylmercaptan and β-chloropropaldehydeacetal; from it the aldehyde was obtained and then γ-methylthiol-α-aminobutyronitrile, from which the amino-acid was easily formed.

The sulphur-containing compounds occurring in the body, for which the intake of sulphur is required, are glutathione, taurine (in taurocholic acid in the bile), chondroitin or mucoitin sulphuric acid (in mucoproteins), and sulphur-containing lipoids: whilst inorganic and ethereal sulphates occur in the urine as oxidation products of the above, with thiosulphates, thiocyanates, taurine, and cystine. In addition, oxidised sulphur is utilised for conjugation with various compounds foreign to the body tissues which might otherwise exert toxic effects.

Deficiency of cystine in the diet of a young animal is reflected in imperfect growth: thus 18 per cent of the protein phaseolin (from the kidney bean) in the diet of the young rat will not support normal growth unless 2 per cent of cystine is added. Again, adult mice will not live on diets deficient in cystine content: inorganic sulphates, sulphur, dithioglycollic and dithiopropionic acids, cysteic acid, and taurine cannot replace the cystine, but dipeptides of the amino-acid are utilised. The loss of sulphur in the urine indicates the necessity for a continuous intake of this element: mucus is also being continually lost from the body and a certain amount of taurine is excreted, although the greater part of the bile acids is reabsorbed from the gut and again excreted in the bile. Our present knowledge suggests that the necessity for a constant supply of glutathione in the cells of the body is the main factor controlling the requirement of cystine, both in maintenance and growth.

Attempts have been made to trace the paths of cystine metabolism by adding it or other sulphur compounds to the diet: by feeding compounds of cystine in which radicles have been added to the amino or sulphhydryl groups or both together, it has been shown that for oxidation to occur, it is necessary that these two groups should be free. Again, from the fact that ingested taurine is excreted unchanged, it appears that deaminisation must precede oxidation of the sulphhydryl group in normal metabolism. These processes probably occur chiefly in the liver, and the three carbon chains left after removal of the sulphur and nitrogen are either converted into protein or glucose (as in the phloridzinised dog) or oxidised completely.

The proportion of ingested cystine retained as such to that oxidised and excreted will depend on the needs of the tissues and on the form in which it is supplied. Greater retention occurs when cystine is given in a combined form, even as a dipeptide, than when administered in the free state, and it is probable that lævo-cystine is better utilised than the racemic form. In fact, the toxic influence on the kidneys of small quantities of cystine is probably due to the fact that the dextro or racemic form has been given, since larger amounts in natural combination in protein are without this effect.

The blood contains sulphur compounds on their way to and from the tissues: in man, about half the sulphur is present as sulphate, inorganic or ethereal, the other half being 'neutral' sulphur and consisting of glutathione (0·1 per cent) and ergothionine, the betaine of thiolhistidine (0·01-0·025 per cent). The physiological function of the latter compound is not known.

Taurocholic acid occurs in much higher concentration in the bile of carnivora than in that of herbivora, but during protein starvation the amount is reduced and glycocholic acid takes its place. In the dog, cystine will not increase the amount of taurocholic acid without the simultaneous administration of cholalic acid, but in the rabbit cystine alone is the limiting factor, its administration resulting in abnormally high concentrations of taurocholic acid in the bile. Free taurine is not further metabolised by the tissues, but in herbivores its administration by mouth results in an increase in the sulphate excretion, since it is decomposed by the bacteria in the large intestine.

Much work has been carried out on the detoxicating effect of oxidised sulphur compounds. The ethereal sulphate of the urine is chiefly potassium indoxyl sulphate and represents the end point of bacterial decomposition of tryptophane in the intestine: the tissues destroy the amino-acid by a different path, since it is completely burnt to its fully oxidised end products. Similarly, administered phenol is excreted in combination with sulphuric acid, but aromatic amino-acids are completely oxidised, so that phenol cannot be in their path of degradation. Certain benzene derivatives are excreted as mercapturic acids in the dog, for example, bromo- or chloro-benzene, but such synthesis probably does not occur in the pig or in man. Phenol and ortho-, meta- and parachlorphenol do not give rise to mercapturic acid formation (see T. S. Hele and co-workers: *Biochem. Jour.*, vol. 20, pp. 598 and 606; 1926: vol. 21, pp. 606, 611, and 628; 1927). When mercapturic acid formation does occur, an abundant supply of cystine is required: this is obtained by feeding the dog on a high protein diet or injecting cystine, but on a low protein diet its formation is much decreased.

Apart from the necessity for a supply of cystine for growth and maintenance, this amino-acid may have an economic importance and become the limiting factor in the suitability of a pasture for the raising of sheep for wool production, since the protein of wool contains upwards of 13 per cent cystine, whilst the food proteins probably contain only 1-2 per cent. Finally, iodine may also become the limiting factor under certain conditions, since there is evidence that thyroid feeding will improve hair growth even in under-nourished animals and at the expense of a further loss of body weight, indicating that a plentiful supply of thyroxine is necessary for hair growth as well as body growth, and that a deficient intake of iodine may decrease the production of wool even if the cystine intake is adequate.

Polyploids and Polyploidy.[1]

By C. D. DARLINGTON.

ANOTHER means of variation, closed to the ordinary diploid, is open to the polyploid. This is variation by loss. Gametes of a diploid which are not equipped with the full chromosome complement are not as a rule functional, but in a tetraploid, where every part of the hereditary material is represented twice in the gametes, loss of a chromosome or part of a chromosome does not necessarily lead to non-viability and is a possible source of a new chromosome balance, a new genetic type. This kind of change is probably responsible for a great deal of the variation in that highly variable species *Tradescantia virginiana*.

It is not surprising, therefore, that many polyploid species, both in breeding behaviour and in chromosome behaviour, resemble this second type, the type of *Primula kewensis*. The hexaploid *Prunus domestica*, having three times the chromosome number of its diploid relatives, itself usually behaves like a diploid, but when it is crossed with one of these diploid relatives the hybrid behaves like a tetraploid of the *Datura* type. Pairing takes

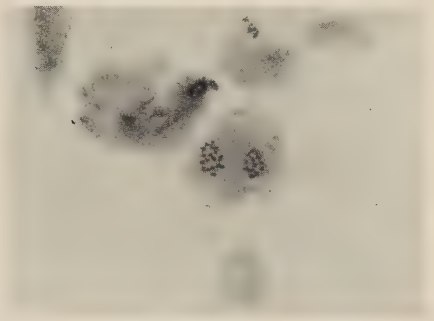

FIG. 5.—Metaphase of the second division in a pollen mother-cell of a tetraploid cherry. As a result of the formation of quadrivalents at the first division, two unequal bodies of chromosomes (13 and 19) have separated.

place not merely between corresponding chromosomes of the diploid and hexaploid, but also between corresponding chromosomes, derived each from the hexaploid, but not normally pairing. In spite of the regularity of chromosome behaviour, this analytic method of investigation is unsatisfactory from the genetical point of view, for the sets of chromosomes of the original diploid parents have probably ceased to be competent by themselves. The processes of variation found in diploids have continued in the polyploid without the same physiological restrictions. The result of splitting up the complement of a polyploid species is therefore sterility.

Hexaploid wheat or oats, when self-fertilised, breeds true in the main, but from time to time seedlings appear having the characters of related species, which have evidently remained submerged so long as the hybrid has behaved like an ordinary diploid. This segregation has been shown to follow the exceptional pairing of homologous but non-

Continued from p. 64.

identical chromosomes, presumably of specifically distinct origin. We must therefore distinguish between the *primary segregation* that results from the normal pairing in a polyploid, and the *secondary segregation* of the characters of its ultimate diploid parents, which results from the exceptional pairing of their unlike chromosomes. The behaviour in these cases is an exact parallel of that in the experimentally produced *Primula kewensis*.

When two hybrid tetraploid species such as *Triticum polonicum* and *T. durum* are crossed, complicated results are naturally to be expected from the combination of these two types of segregation. As in the *Prunus* hybrid, not two species but four are really concerned, and *a priori* we can have no reason for predicting one kind of pairing and segregation rather than another. Breeding results show that, in respect of certain chromosomes at least, there is regular pairing of the chromosomes derived from the ultimate diploid parents of each species, with the consequent segregation of their characters, and the suppression of the characters of the immediate tetraploid parents, which are never recovered in subsequent generations.

A hybrid in *Rubus* shows another complexity in segregation. Three seedlings were raised from a cross between the diploid *R. rusticanus inermis* and the tetraploid *R. thyrsiger*. Two of these were indistinguishable and, as might have been expected, closely resembled the tetraploid parent; they were triploid. The third, although obviously a hybrid, resembled the diploid parent more closely in seven well-marked characters which chiefly distinguished the two parental species. This seedling was tetraploid, and evidently the result of the union of a normal reduced male with a diploid female gamete. Thus where the female parent had made a double contribution of hereditary material, its genetical influence was increased.

This tetraploid seedling was fertile; the triploids were, as usual, sterile. In its breeding it showed two types of segregation: first a random segregation with the recovery of approximately 1 in 36 of the quadruplex recessive; secondly, the complete suppression of the characters of one parent. These results would be expected if the several chromosome types of the two species had varied independently, so that in one type there was indifferent affinity, in another a rigidly determined system of pairing. The behaviour of this cross, in both the first and second generation, affords a neat example of the application of the chromosome theory to the theory of interspecific hybridisation.

It may be worth while pointing out that, in so far as there are species in *Rubus*, this fertile seedling is a new species. Similarly, in so far as there are species in *Primula*, *P. kewensis* is a new species, and, in so far as there are species or genera in the *Cruciferæ*, the *Raphanus-Brassica* tetraploid is a new species or a new genus. Polyploidy is therefore evidently a means of species-formation. Its

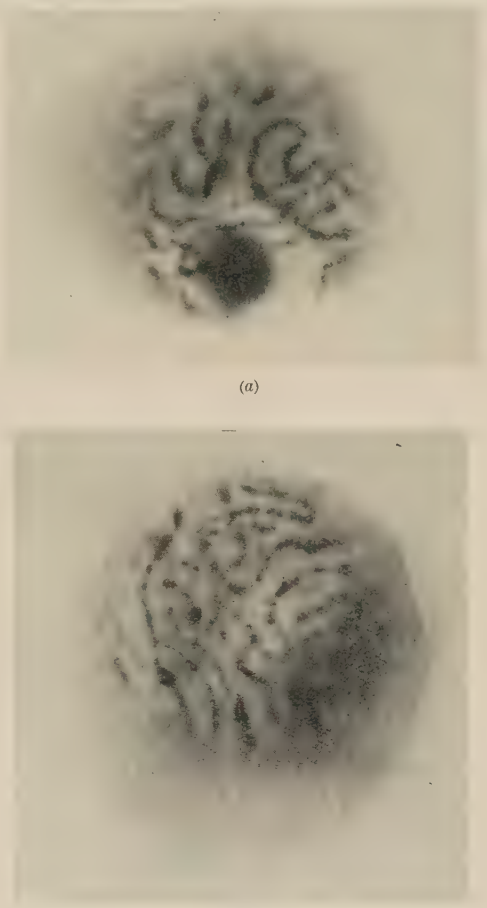
mportance in evolution is more doubtful. Poly-oids in their origin pass through a process that is rtually irreversible, and the advantages of their culiar properties are therefore to a great extent eretricious. But if polyploids are not themselves evolutionary importance the occurrence of poly-oidy is probably a symptom of evolutionary ocesses, such as hybridisation, that are of great mportance. Moreover, polyploids afford a field for e study of the hereditary material under con-tions which apply critical tests of its properties. nese must now be considered.

Since not merely the fertility of a polyploid but so the genetical behaviour in every other way epends on the pairing of its chromosomes, the nditions of this pairing are well worth our study. nese conditions are evidently not simple, for romosomes may regularly pair in certain circum-ances (as in the diploid *Primula kewensis*), but rely pair when identical mates are available. nis problem we may shelve by saying that pairing epends on 'relative affinity'. But we may also t, as in triploid *Hyacinthus* and tetraploid *atura*, the failure of association of chromosomes nown to be identical or nearly so.

This problem, evidently related to the other, is t so easily dismissed. To understand it we must amine the processes leading up to 'metaphase' the reduction division at which pairing is chiefly udied. At an early (prophase) stage in *Hyacin-us*, three or four threads, according to the mber of corresponding chromosomes of a rticular type, are seen to *pair*; that is to say, ch part of each thread takes as partner a corre-onding part of one of the other threads, and, rthermore, in doing so it acts independently of ctions higher up and lower down the thread (see g. 6). We find, with three threads, one of the ree is always unpaired, but it is a different one the three that is unpaired at different points. ith four threads interchanges of partner occur nongst them. Thus pairing depends not on any neral affinity of the chromosomes for one another, t on the capacity of the individual parts of the romosomes to pair. This seems equally clear from e results of genetical analysis of the forms of *osophila*, in which parts of chromosomes have been versed. The basis of the affinity of chromosomes ems then to be similar arrangement of their rts. A dissimilar arrangement giving a lower inity need not necessarily be correlated with netic differentiation, but it nearly always will be, it will indicate different descent.

Let us now see why these chromosomes, which obably always pair at prophase, fail to associate metaphase. In the triploid hyacinths the failure form a trivalent falls almost exclusively on romosomes of a short type, and similarly with adrivalents in the tetraploid. If the pairs formed this type of chromosome are compared with ose of the longer types, it is seen that they are atively simple. Both kinds consist of four romatids' or halves of longitudinally split romosomes associated in pairs, but in the longer romosomes these chromatids change partners, forming what are called 'chiasmata,' two, three, four, or five times. In the short chromosomes, on the other hand, there is rarely more than one chiasma.

The chiasmata are formed at random both as regards number and position, and with an average frequency proportional to the length of the chromosome. Only by the failure of a proportion of chromosomes to form any chiasmata at all can this



(*a*)

(*b*)

FIG. 6.—Conjugation of chromosomes in a triploid tulip. (*a*) Chromosomes lying parallel in threes before association. (*b*) Chromosomes associated in pairs with exchange of partners.

normal frequency be maintained in the short type, for one of the three chromosomes must be associated with the other two and have two chiasmata.

The expected proportion of failure agrees approximately with the proportion (about one-fifth) of unpaired short chromosomes found. It therefore seems probable that pairing fails merely because no chiasma is established. This implies that the relationships of the chromatids at reduction are the same as at ordinary mitosis; they are attracted in pairs. The association of the chromosomes is then the result of a failure of the pairs of chromosomes that conjugated at prophase to separate, in respect of their constituent chromatids, as they came together.

If this is generally true, then short chromosomes

newly arisen by fragmentation should fail to pair regularly, and this is so wherever it has been studied, as in *Secale*, *Zea*, and *Tradescantia*. Such variation in pairing is analogous to that found in hybrids and polyploids, for in all these types the length of the chromosome pairing at prophase is reduced as compared with that in the non-hybrid diploid. It may be reduced so that in a proportion of cases chiasma-formation, and therefore pairing, fails altogether. From the opposite point of view we may say that the mechanism of reduction is fitted to give a regular segregation of chromosomes of the normal types in a non-hybrid diploid.

It would be possible for dissimilar chromosomes to pair along a sufficient length to establish a single chiasma, in the absence of competition, but with competition in a polyploid, clearly a chiasma will be most likely to be formed between the pair which is capable of association through the greater length. Differential affinity can therefore be regarded as a measure of linear identity. In this way the behaviour of the chromosomes, derived from different species, which rarely pair in tetraploid *Primula kewensis* or hexaploid *Prunus domestica*, yet always pair in the diploid *Primula* or the tetraploid *Prunus* hybrid, is intelligible in more or less physical terms.

We have emphasised what may be called the mechanical conditions which determine the origin and variation of polyploids. This is because the physiological conditions are already widely recognised, and are not specific to polyploids, but in the study of polyploids the two types of restriction on the origin of new forms are equally evident, and it is impossible to show that one is more important than the other. Each has a final effect, and nowhere yet has any clear relation been shown between them.

This sketch of certain features of their behaviour should show that the investigation of polyploids is of importance, not merely in determining their own peculiar properties of inheritance and variation, but also in making out principles of behaviour that are equally important in the diploid organism.

Giant Aeroplanes and their Design.

THE giant aeroplane has always influenced the mind of the engineer as well as of the layman in a manner altogether out of any proportion to its practicability. Like all other structures, animal or mechanical, it is subject to the inexorable law of Nature known to engineers as the 'law of the cube'. For an established design of aeroplane with materials of unchanged quality, the law of the cube is not seriously disputed. If the proportion of useful load is plotted against surface and engine power, a well-defined family of closed isobars is obtained shrinking to a conjugate point of maximum useful load. For a braced biplane of wood with a factor of safety of 4 to 5, five tons total was a reasonable limit in pre-War days. An accumulation of detail improvements has put up this figure to seven or eight tons total weight, the disposable weight, including fuel, being about two-fifths of the total weight, and the paying load for five or six hours' flight being roughly one-fifth.

If instead of considering the useful load by itself it is considered as a fraction of the total weight, a very different conclusion is reached. The smaller the aeroplane the greater is the proportion of useful load until the indispensable weights—pilot, instruments, etc.—become a serious proportion of the total weight. A competent judge with wide experience has given the opinion that the best size from the point of view of useful ton-miles is less than two tons total weight.

The weak point in the argument is that the estimation of structural weight and aerodynamical quality is necessarily based on the best current practice, and though it is unlikely that all the competing designers in the world have missed any serious point in the theory or practice of structural design, still the possibility remains and is the standby of those who advocate the possibility and indeed the superiority of giant aeroplanes.

The history of these efforts is not encouraging. It is not necessary to refer to the positive disasters which marked the first flight of most of the early giants. Taking only recent designs, although a number of ten to fifteen ton aeroplanes and flying boats have flown and landed without accident, and have proved at least controllable in the air, yet there has not been put forward the slightest evidence that the performance as measured by useful ton-miles has increased, and much evidence that the relative performance, useful ton-miles per ton of total weight, has fallen off badly, in the very way predicted by the law of the cube.

The latest effort to break away from the natural limitation of size is that of the well-known German designer, Dornier. In a recent paper to the Royal Aeronautical Society, he announced the construction of a giant flying boat with twelve engines, distributed along the span, in pairs, with a total power of about 5000 kw. and a total flying weight of about 50 tons. It is now announced that this real giant among flying machines has successfully arisen from and alighted on the surface of Lake Constance.

The distribution of weights along the wing is an old device for reducing the stresses on the wings in steady flight. As in all other cases of design where a compromise has to be made between conflicting requirements, this is offset by a corresponding disadvantage that the stresses in a landing, especially in an unequal landing, are increased. The wing structure is thus exposed to reversed stresses of a severe and indeterminate kind. Other serious disadvantages follow.

The device has failed in previous attempts. It is advisable to wait for authenticated test evidence before accepting the truly revolutionary forecasts made by the designer, of which the most astonishing is the increase of useful ton-miles with size without limit, not merely absolutely but in proportion to total weight.

Obituary.

MR. M. R. OLDFIELD THOMAS, F.R.S.

MICHAEL ROGERS OLDFIELD THOMAS, who died in tragic circumstances on June 16 at the age of seventy-one years, was from boyhood devoted to the study of natural history. In 1876, at the age of eighteen, he was appointed to a clerical post in the British Museum. During the two succeeding years he devoted his leisure to biological studies under Huxley at the Royal College of Science and soon proved himself to be an alert observer with most capable hands. His beautiful dissections, and the ease and speed with which he made them, soon won the admiration of his teachers; and their reports persuaded Dr. Günther, the Keeper of Zoology, to arrange for the transfer of Thomas from the clerical to the scientific staff of the Museum. Thomas used to tell an amusing story of that transfer. For some months he was aware that it was going to take place; and rumour told him that he would work in future at echinoderms. Accordingly he took up the study of echinoderms with enthusiasm. At last the great day dawned. Dr. Günther sent for him and said: "Thomas, you will do the mammals." Poor Thomas murmured something about echinoderms, but the autocrat thundered: "You *will* do the mammals." Visions of countless sheep and cattle rushed into the lad's mind and, as Thomas put it, he hated those animals from a systematic point of view for ever more.

Günther never made a wiser decision as it turned out. He was himself greatly interested in the Mammalia, and he thought that the keen, sharp-sighted boy would be just the person to help him to continue the solid contributions he was making to systematic literature on Mammalia. But the skirts of a great keeper's cloak were not ample enough to conceal for long the enthusiastic and ambitious Thomas. Günther had intended to write the Museum Catalogue of Marsupialia and Monotremata himself; but Thomas made so many discoveries and worked with such energy and painstaking thoroughness that Günther willingly relinquished the task to him. In 1888 the Catalogue was published, and it remains to this day the solid foundation of all modern systematic work on the group.

Two events which profoundly influenced Thomas's subsequent career happened in or about 1890. Before that time mammal collections consisted chiefly of spirit specimens and of specimens stuffed with their skulls inside. The Biological Survey of the United States Department of Agriculture had just been established under the leadership of Dr. C. Hart Merriam, and the first reports under the serial title "North American Fauna" were just beginning to appear. Attracted by these, Thomas found that Merriam was working with long series of carefully prepared dried skins, each skin accompanied by its own cleaned skull. Correspondence followed and Thomas decided to give the new methods a trial. In the course of the next few years he perfected them. Leaving North America in the competent hands of the Americans, Thomas resolved that the British Museum should attempt a survey of the mammals of the rest of the world—a big task for one institution with limited means and for one rather frail man to undertake.

After his marriage to Mary Kane, daughter of Sir Andrew Clark, in 1890, Thomas was in possession of considerable means. His wife, interested in natural history herself and devoted to all that concerned her husband, readily agreed to the use of as much as could be spared from their joint purse for the purpose of financing collectors of mammals in various parts of the world. They went, too, on collecting trips together into various parts of western Europe and to South America. Quickly Thomas gathered round him a band of volunteer workers in the Museum; and by hard work and perseverance he gained the ears and the purses of many wealthy people who were glad to benefit the national collections and advance the cause of science.

Gifted with an extremely practical mind, Thomas was able to cut out all unessentials; in each problem that came to him for solution he saw at once the point and the shortest way to it. He worked with amazing rapidity, jumping from one matter to another without hesitation or confusion of ideas, and he never forgot anything of importance. A continuous stream of papers flowed from his pen in the *Annals and Magazine of Natural History* from 1880 down to the present year, with many contributions to the *Proceedings of the Zoological Society* and the *Journal of the Bombay Natural History Society*. Meeting that keen naturalist the late R. C. Wroughton in 1909, they developed together the well-known Mammal Survey of India, by which huge collections of Indian mammals have been brought together and worked out, resulting in a vastly extended knowledge of this part of the zoology of India and the adjacent countries.

In all, Thomas described more than 2000 species and defined more than 200 genera of mammals. His papers are models of terse description with nothing superfluous anywhere. Indeed, over and over again he might have said a little more with advantage; but there was always another job waiting to be done and he had said enough for the present purpose. Always busy and somewhat difficult to approach, people who knew him only by his scientific writings regarded Thomas merely as a narrow systematist and a "mere museum naturalist". No greater error was ever made; he was at heart a field naturalist, and on his various journeys made important collections of flies and myriopods in addition to his mammals. But with a big task before him, he deliberately restrained his natural inclinations, saw clearly what he had to do, and lived just long enough to do it. His work has built the unrivalled national collection of mammals and the vast literature relating to it.

In order to accomplish his life's work, Thomas refused to entertain any thought of official promotion. Elected an F.R.S. in 1901, he served on the council of the Royal Society, and for many years

on the council of the Zoological Society of London. After his official retirement from the Museum in 1923, he continued his old work as though nothing had happened. The death of his wife in May 1928 was a severe blow from which he never recovered.

M. A. C. H.

PROF. HENRI ANDOYER.

BY the death on June 12 of Marie Henri Andoyer at the age of sixty-six years, French science has lost a distinguished member of that characteristic school of mathematical astronomers of which such men as Tisserand and Radau were eminent examples and Henri Poincaré the most brilliant ornament. In Andoyer a rare combination of qualities was united. To his knowledge and ability as a mathematician and his acquaintance with the technical side of practical astronomy he joined a skill and a passion for numerical calculation which recalls the kindred taste of J. C. Adams in England. He was at the same time a gifted teacher, with an enthusiasm and critical sense which made his exposition equally attractive in the shape of lectures or in published form.

Andoyer was born at Paris on Oct. 1, 1862, and entered the École Normale Supérieure in 1881, devoting himself to the study of pure mathematics. The years 1885–92 were spent at Toulouse, where Andoyer was attached to the Observatory but more actively engaged as professor in the faculty of science. As astronomer, however, he took part in organising the work of the Astrographic Chart, and attended the early conferences on the scheme at Paris. In 1892, before this work had advanced beyond the preliminary stages at Toulouse, Andoyer was recalled to Paris to deliver a course of lectures on mathematical astronomy and celestial mechanics and to share in the teaching of mathematics in the Faculty of Science. To this period belongs his "Leçons sur la théorie des formes et la géometrie analytique supérieure", together with a number of more elementary text-books and some original papers, all devoted to pure mathematics. It was thus comparatively late in life that his devotion to mathematical astronomy asserted itself as an absorbing study, and even after 1903, when he was appointed professor of astronomy at the Sorbonne, his interests were not always confined in any narrow sense to the subject of his chair. The germ to be seen so early as 1887 in a paper on intermediary orbits, inspired by the work of Gyldèn, was a little slow in bearing fruit.

In 1910, Andoyer succeeded Bouquet de la Grye as a member of the Bureau des Longitudes, and on the death of Radau in the closing days of 1911 followed him as editor of the *Connaissance des Temps*. The annual ephemeris has appeared under his direction from the year 1914 onwards, and has fully maintained the high reputation earned for it under his predecessors.

Two works of permanent value embody the substance of Andoyer's teaching. One, "Cours d'astronomie", comprises a first volume on theoretical astronomy, which reached its third edition in 1923, and a second on practical astronomy, of which the second edition, in collaboration with A. Lambert, appeared in 1924. The other, "Cours de mécanique céleste", in which stress is laid on the computational side of this intricate subject, was published in two volumes (1923 and 1926).

The theory of the moon's motion, after the work of Delaunay and Radau on one hand, and of Hill and E. W. Brown on the other, presents a field offering little scope for easy or striking achievements of a novel kind. But it was to this difficult and in appearance fully explored problem that Andoyer turned repeatedly with complete knowledge of what had been done by others. It is the subject of his last considerable work, "Sur la théorie analytique du mouvement de la lune", the culmination of a series of critical studies in a branch of astronomy for which he was exceptionally qualified by natural gifts.

Andoyer's passion for numerical calculation found scope in the recomputation of fundamental logarithmic and trigonometrical tables. Executed single-handed and with remarkable rapidity, equal evidence of unfailing industry and quite extraordinary skill, these tables were published between 1911 and 1918. It is likely that they will not be superseded by any later work of the same kind, at any rate performed in the same fashion.

Andoyer was elected an associate of the Royal Astronomical Society in 1914 and became a member of the Paris Academy of Sciences in 1919. He was Officier of the Legion of Honour. Of a modest and simple disposition, he will be mourned by a circle of colleagues, and his death removes from the ranks of astronomy a gifted and indefatigable worker not easily replaced.

H. C. P.

WE regret to announce the following deaths:

Mr. W. S. Andrews, at one time associated with Edison in electrical developments and distinguished for his work on fluorescence and phosphorescence and selenium cells, on July 1, aged eighty-one years.

Dr. Charles F. Brush, of Cleveland, Ohio, the inventor of the electric arc light known by his name, on June 15, aged eighty years.

Prof. Wilhelm Ellenberger, formerly rector and director of the physiological and histological institute and of the physiological chemistry research station of the Veterinary Highschool, Dresden.

Lieut.-Colonel George Henderson, formerly of the Indian Medical Service and for a time Director of the Royal Botanical Gardens and professor of botany in the University of Calcutta, on June 24, aged ninety-two years.

Major C. V. Hodgson, hydrographic and geodetic engineer and assistant chief of the division of geodesy, U.S. Coast and Geodetic Survey, who had taken part in many surveying expeditions to the waters of Alaska and the Philippine Islands, and was known chiefly for his work on geodetic astronomy, on May 19, aged forty-nine years.

Mr. G. R. Kaye, formerly of the Indian Education Department, author of some well-known works on Indian astronomy.

M. Léon Lindet, member of the Section of Rural Economy of the Paris Academy of Sciences, known for his work on the physiology of plant and animal foodstuffs, on June 16, aged seventy-two years.

News and Views.

We have referred from time to time in these umns to the importance of scientific research in the velopment of the British Empire overseas and to work in this connexion of Mr. L. S. Amery d Mr. W. Ormsby-Gore, Secretary and Under-cretary of State for the Colonies respectively in recent Conservative Government. That there is be continuity of effort and to some extent of icy by the present Government appears probable m the speech made by Mr. J. H. Thomas in the use of Commons on July 12 last, in moving a olution, which was agreed to, "authorising the easury, on the recommendation of a Committee to appointed by the Secretary of State, to make vances, either by way of grant or by way of loan, the Governments of certain Colonies, territories der his Majesty's protection, and mandated terri-ies, for the purpose of aiding and developing riculture and industry in the Colonies or territories d thereby promoting commerce with or industry the United Kingdom". The resolution authorises annual payment of not more than one million nds, and Mr. Thomas has in mind a small but ive committee to allocate the grants. An un-pended residue in any year will not be available the succeeding year. Mr. Thomas thinks that eeding up colonial development will provide much ful work in Great Britain; indeed, the scheme is rt of his plan for dealing with unemployment nerally.

In the discussion of Mr. Thomas's resolution, Mr. nery specifically raised the question of scientific earch, health campaigns, etc., and obtained an urance from Mr. Thomas that nothing which could called 'development' would be excluded. Mr. nsby-Gore also referred to this question, and stated t research undertaken under this resolution should in relation to purely local problems or those ecting a group of colonies only and, as such, outside purview of the Empire Marketing Board. Mr. omas stated that the risk of overlapping the work the Empire Marketing Board has been foreseen, he does not anticipate difficulty from this cause. ch was said during the debate about industrial velopment and little about scientific research, which s necessary antecedent. Mr. Thomas has promised mall committee of "knowledge and experience". viously, the successful working of the scheme will pend almost entirely on the composition of this mmittee; we trust, therefore, that some members least will have "knowledge and experience" of prime necessity of scientific research in the velopment of tropical countries.

A lecture with demonstrations was given by J. C. Bose on July 9 at the India Office, the Right n. Wedgwood Benn, Secretary of State for India, ng in the chair. Sir J. C. Bose thinks that the chanism of life can best be studied in the more damental and earlier form presented in plants. s can only be realised by exceeding the range of perception of our organs of sensation by means, for example, of his 'contraction recorder' which it was stated, produces a magnification of fifty million times. Great as this is, it may be mentioned that, even before the advent of the thermionic valve, the combination of optical and electrical methods had exceeded this magnification and that optical methods of recording exhibit superiority over mechanical means from the point of view of freedom from inertia, time-lag, and speed as well as magnification. An experiment was performed which included the chairman and the stem of a lupin plant in series with the secondary of a small induction coil; the interrupted primary current was gradually increased and the plant stem was found to bend before the human subject objected to the strength of the electrical stimulus. This does not necessarily show, however, that the plant was more sensitive than the human being; whereas the plant early exhibited locally unequal degrees of mechanical contraction as a result of electrolytic changes at the site of passage of an electric current, the human being experienced a sensation which, in the usually accepted terminology, involves a change in consciousness. A valve voltmeter or a thermo-vacuo junction included in the same circuit would have proved more 'sensitive' than either plant or animal.

It is perhaps well to make it quite clear that the term sensitivity has quite a different connotation in physiology from that which it has in physics; it would thus appear that the so-called sensitivity of plants, for example, to light, gravity, and electrical, mechanical, and chemical stimuli, is of the purely physical type and must obviously remain so as long as we regard consciousness as the discriminating attribute between animal and plant. Other experiments of Sir J. C. Bose have led him to assign to plants nervous and cardio-vascular systems. One such experiment was demonstrated: the stem of a drooping lupin leaf was placed in a tube of water and camphor was added to the latter. The erection of the leaf in a jerky manner (responding just like a crinkled balloon to steady inflation) was presumed as evidence of the existence of a pulsatile organ in the plant causing the ascent of sap. A consideration of the purely physical action of camphor, for example, on surface tension would merit attention in this connexion. Seeing Sir J. C. Bose's demonstrations, it is impossible to question the occurrence of the phenomena he describes; but animal physiologists will not readily accept his interpretations. Sir J. C. Bose also showed pictures of the Bose Research Institute at Calcutta. It is to the co-operation of workers trained in this and similar institutes with the intellect of Britain that Sir J. C. Bose looks for the solution of the common difficulties of the two nations.

The Devonport Pathological Laboratories of the Seamen's Hospital, Greenwich, together with a new Nurses' Home, were opened by their Royal Highnesses the Duke and Duchess of York on July 15. The

laboratory building is constructed of sand-faced red brick and stone from designs by Sir Edwin Cooper, the cost being defrayed out of a fund collected by Lord Devonport. The laboratories on two floors are placed around a central entrance hall and staircase. The lower floor accommodates two staff laboratories, a large preparation room fitted with boilers, hot-air and steam sterilisers, autoclave and serum inspissator, and the office, and at either end a large room is allocated as museum and library respectively. An animal house and a workshop are located in a short southern wing, and mortuary (with cold storage), post-mortem room, and class-room for operative surgery in a corresponding northern wing. The upper floor accommodates two staff laboratories with rooms for assistants, a biochemical laboratory with balance and dark rooms attached, and several smaller rooms for research workers. The flooring throughout is of wood block, except in the entrance hall; the working benches are of teak, and are supplied with water, gas, and electric current (light and power), and internal and Post Office telephones are installed in each laboratory. The equipment of centrifuges, incubators, microscopes, microtomes, and glass apparatus is very complete. Heating is by hot-water radiators supplied from the boiler-house near by, in which is also a gas incinerator for destruction of waste and infective materials.

IT is reported in the *Times* of July 15 that a charter for the constitution of trustees to administer the National Radium Fund and to provide for the duties of the National Radium Commission, has been granted by the Privy Council. The charter makes provision for the election of trustees of the radium and for an executive body to be known as the National Radium Commission. The trustees will hold all the moneys and buy therewith and hold radium for use by this Commission. The duties of the Commission will be to deal with the distribution and use of all radium held by the trustees, having regard to the advancement of knowledge and economy of use; and to approve plans for the use of radium for medical treatment and research. It is thus seen that the duties of the Commission are wide ones and the granting of this charter marks a very important phase in the development of radiology in Great Britain.

UNDER the auspices of the Beaux Arts of France, and with the concession granted by the French Republic to dig at Combe-Capelle in a remarkable Moustierian site, Dordogne District, the Canadian School of Prehistory has just opened its season for 1929, headquarters being at the classic site of Les Eyzies de Tayac. The season of 1928 proved so fruitful in results that the School was enabled to install in several museums of the universities of Canada collections illustrating the activities and industries of early man from the Ipswichian (pre-Chellean) to the Robenhausian Period. Of the problems remaining to be solved in the Moustierian Period, the Canadian School was fortunate enough to obtain evidence in four distinct zones below the "Vieux Moustierien" of the classic section of Le Moustier, which add new information to the facts already known with respect to Moustierian man (Neanderthal). After careful inspection of all the collections made by the Canadian School in France by the Administrator of the Beaux Arts in the Dordogne District (M. Peyrony), the Laboratory of Geology and Palæontology at Ottawa, the School's headquarters in Canada, was further replenished with about 8000 specimens for distribution.

THE School in 1928 visited many of the sites of the Dordogne, Charente, and Pyrenees sections of France, under the guidance of M. Peyrony, Count Begouen, Dr. Henri Martin, Abbé Breuil, and others. By special invitation to visit and explore the Neolithic site of Ryckholt (Ste. Gertrude) in the highlands of Holland, the Canadian School was able to add an excellent series of specimens to its collections for Canadian universities. A movement is now on foot in Canada to incorporate by Act of Parliament the Canadian School of Prehistory, with the object of backing up the work that has been done and is being done by the School in France. The movement is led by Dr. E. R. Cameron, K.C., of the Supreme Court, and a number of leading archæologists and ethnologists of the Dominion. One of its chief objects will be the investigation of prehistoric sites in the northern districts of Canada where the Eskimos and the reindeer, with the musk-oxen, great stag, and bisons, are found to-day, all well-known types of life which once lived in south-western France in Magdalenian times. The Canadian School welcomes visitors to the site at Combe-Capelle where the excavations are going on, and especially those from the British Isles and other parts of the Empire interested in prehistory.

THERE is a demand for radio telephone sets by owners who can pilot their own aeroplanes. The sets used by commercial aircraft are much too heavy for light aeroplanes. The transmitter must have a range of at least fifty miles when communicating with the ordinary aerodrome ground station and a hundred miles when communicating with a large station like the one at Croydon. The Marconi Co. has now designed a set to meet these requirements. It combines a telephone transmitter and receiver in a compact wooden box the dimensions of which are only 16 in. by 9 in. by 7 in. Its weight, including that of the wind-driven generator, accumulator, aerial and connecting leads, is only 60 lb. The set has been designed for the transmission of telephony only. Pilots have quite enough to do in flying their machines and watching their instruments without the added labour of interpreting telegraph signals in the Morse code. The set may be installed for operation by the passenger or it may be fitted in any convenient part of the aeroplane and operated by the pilot through a 'remote control'. In the latter case there is only a one-handle manipulation. Seeing that private air cruising on business and pleasure is rapidly becoming popular, we welcome this device. Advice regarding the state of the weather and the conditions at the various aerodromes will now be available to light aeroplane tourists. In addition, they will now have a valuable means of position finding when flying over parts of the Continent and other places where there are aerodrome

round stations fitted with direction finders. We hope at the international regulations enforcing adequate dio facilities on commercial aircraft will now be forced on privately owned aeroplanes.

IN August next the *Discovery* will set out once gain on a voyage of exploration and scientific discovery to the Antarctic continent. The enterprise, hich is under the leadership of Sir Douglas Mawson, being sponsored by the British, Australian, and ew Zealand Governments, and considerable assistnce in money and kind has been given by private dividuals and firms, both in England and Australia. r. MacRobertson, a wealthy manufacturer in Melourne, has contributed £10,000 to the funds of e Expedition, and several other private subscribers e assisting, but no general appeal to the public is eing made for funds. The *Discovery* is now being verhauled at the West India Docks, and is being ted with all the essential scientific gear that the rthcoming expedition makes necessary. Capt. J. K. avis, who has been lent by the Government of the ommonwealth of Australia, has been appointed aster, and will also act as second in command of the pedition. He was associated with Sir Douglas awson in a similar capacity on the pre-War Australian Antarctic Expedition and has special and tensive experience in the Antarctic coastal and pack- waters. The scientific personnel and crew will umber about forty. The vessel will carry an aeroane with floats for rising from and alighting on the a (where open water makes this possible), and ternatively will use a ski undercarriage for use on e or snow. The aeroplane will be used for scouting, r photographing the coast-line, and for general urposes as a 'long arm' of the expedition. The ip will be equipped with powerful deep trawling ar and with echo-sounding apparatus. Both longave and short-wave wireless equipment will be rried. The expedition will carry out hydrographic rvey work, and will study meteorological conions with the view of discovering any relationship tween those conditions and the climate and weather Australia. It will also carry out investigations of e fauna, notably whales and seals, of the region plored.

DR. WILLIAM HUME-ROTHERY has been elected to e research fellowship in metallurgy of the Armourers d Brasiers' Company in succession to Dr. Constance Tipper.

THE Autumn Lecture of the Institute of Metals ll be delivered during the forthcoming Düsseldorf eeting on Sept. 5 by Mr. A. G. C. Gwyer, who will eak in German on aluminium and its alloys.

THE following appointments have recently been ade to the Imperial Bureau of Soil Science: Scientific sistant, Mr. A. J. Lloyd Lawrence; assistant for anslations, Miss H. Sherbatoff.

MR. H. T. TIZARD, permanent secretary of the epartment of Scientific and Industrial Research, s been appointed rector of the Imperial College of Science and Technology as from the beginning of September in succession to Sir Thomas Holland.

WE learn from Miss C. J. Vivian, 4 Dolcoath Road, Camborne, Cornwall, that a vigorous tremor was experienced at about 7 P.M. on July 7 in various parts of Camborne. In a church at Penponds, near Camborne, the vibration was so intense that the rafters creaked audibly. Old tin-mine workings undermine a part of the town, but a subsidence of the soil due to this could scarcely cover the district affected.

THE following have been elected officers for the session 1929–30 of the British Institute of Radiology incorporated with the Röntgen Society—*President:* Mr. C. Thurstan Holland; *Past Presidents:* Sir Humphry Rolleston and Dr. G. W. C. Kaye; *Vice-presidents:* Sir William Bragg, Mr. L. A. Rowden, and Major C. E. S. Phillips; *Honorary Treasurer:* Mr. D. B. McGrigor; *Honorary Secretaries:* Dr. Stanley Melville and Dr. G. Shearer; *Honorary Editors:* Dr. G. W. C. Kaye and Mr. R. J. Reynolds.

THE annual report and accounts for 1928 of the Ross Institute and Hospital for Tropical Diseases, Putney Heath, S.W.15, has been issued. The Institute was founded primarily to carry out research work in the prevention and treatment of tropical diseases, and is supported entirely by voluntary contributions. An account is given of the visit of Sir Malcolm Watson and Major Stevens to India and Ceylon for the purpose of advisory and propaganda work on malaria, and of the research work carried out in the Institute.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A head of the Engineering Department of the Leicester College of Technology—The Registrar, College of Technology, Leicester (July 22). An assistant county agricultural organiser under the Hampshire Agricultural Education Committee—The Agricultural Organiser, 82 High Street, Winchester (July 24). A head of the Mechanical Engineering Department of Robert Gordon's College, Aberdeen—The Secretary and Registrar, Robert Gordon's College, Aberdeen (July 29). An assistant lecturer in physics in the University of Leeds—The Registrar, The University, Leeds (July 29). A lecturer in pharmacy in the Department of Chemistry of the Witwatersrand Technical Institute—Messrs. Chalmers and Guthrie, Ltd., 9 Idol Lane, E.C.3 (July 31). An assistant lecturer in the Department of Chemistry of the University of Birmingham—The Secretary, The University of Birmingham (July 31). A superintendent of the Burma Civil Veterinary Department—Secretary to the High Commissioner for India (General Department), 42 Grosvenor Gardens, S.W.1 (Aug. 4). A lecturer in physiology in the University of Birmingham—The Secretary, The University, Birmingham (Aug. 5). A demonstrator in civil and mechanical engineering in the Department of Engineering of the University of Leeds—The Registrar, The University, Leeds (Aug. 5). Two timber assistants for the Utilization Forest Circle, Commercial Concern, Burma—The Secretary to the

High Commissioner for India, General Department, 42 Grosvenor Gardens, S.W.1 (Aug. 10). A lecturer in mineralogy and petrology in the University of Reading—The Vice-Chancellor, The University, Reading (Aug. 14). An assistant plant pathologist under the Department of Agriculture and Forests of the Sudan Government—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, S.W.1 (Aug. 15). An assistant superintendent in the Archæological Survey Department of the Government of India—The Secretary to the High Commissioner for India, 42 Grosvenor Gardens, S.W.1 (Aug. 17). A professor of geology and mineralogy in Rhodes University College, Grahamstown—The Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, Trafalgar Square, W.C.2 (Aug. 31). A research assistant in the Colour Chemistry and Dyeing Department of the University of Leeds—The Registrar, The University, Leeds (Sept. 2). A professor of clinical pathology in the Egyptian University, Cairo—The Dean, Faculty of Medicine, Egyptian University, Cairo (Sept. 15). An assistantship in natural history—The Secretary, University College, Galway (Sept. 21). An assistant director of the Technological Library of the Indian Central Cotton Committee, Bombay—The Secretary to the High Commissioner for India, General Department, 42 Grosvenor Gardens, S.W.1 (Sept. 29). Part-time lecturers in market research and sales management at the Polytechnic, Regent Street—The Director of Education, The Polytechnic, Regent Street, W.1. A head of the pathological division of the Rubber Research Institute of Malaya—The Secretary, London Advisory Committee, Rubber Research Institute of Malaya, 2-4 Idol Lane, Eastcheap, E.C.3. A lecturer in mathematics at the Gordon College, Khartoum—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, S.W.1. A full-time chief instructor of the Printing Department of the North-Western Polytechnic, Prince of Wales Road, Kentish Town—The Secretary, North-Western Polytechnic, Prince of Wales Road, N.W.5. An assistant master to teach mathematics in the Junior Technical School for Boys of the Woolwich Polytechnic—The Principal, Woolwich Polytechnic, S.E.18. A teacher of telephony in evening classes at the Woolwich Polytechnic—The Principal, Woolwich Polytechnic, S.E.18. A chief officer for the Imperial Agricultural Bureau for Plant Genetics: Herbage Plants—Prof. R. G. Stapledon, Agricultural Buildings, Aberystwyth.

Our Astronomical Column.

July and August Meteors.—Mr. W. F. Denning writes: "The season for meteoric abundance has now opened and a large number of showers are visible, including the early phase of the great Perseid display. The latter appears to be visible during the whole of July and August with a maximum on Aug. 11 or 12. Probably the morning of the latter is the period when most meteors will be visible. The present year seems likely to be favourable for the occurrence of many meteors, for an abundant maximum of 250 per hour for one observer was counted in 1921 on the early morning of Aug. 12. The earth will occupy very nearly the same position in its orbit on the morning of Aug. 12 next, and the shower may be repeated if the density of the part of the stream encountered is about equal to that through which the earth passed eight years ago. This may be doubted, however, though there are slight evidences of an eight-year period in the character of the display and observations may prove specially interesting. The Capricornids (July 19–Aug. 6) with radiant at 304° – 11°, and the Aquarids (July 24–31) radiant 338° – 11°, usually form two of the principal displays of the July–August period; but there are some hundreds of others exhibiting various degrees of strength, though the majority are very attenuated and are only to be recognised by long and accurate observation."

Ancient Greek Astronomy.—M. E. M. Antoniadi contributes an article to *L'Astronomie* for May in which he points out that several of the philosophers of ancient Greece anticipated the conception of universal gravitation. Anaxagoras, Plato, Aristotle, and others perceived that massive bodies exercised a force directed towards their centres. Aristotle ascribed the tides to the action of the sun. Anaxagoras and Empedocles recognised that the centrifugal tendency of a revolving body, such as the moon, enabled it to circulate round a central orb without falling into it. While these conceptions were quite sound, it does not appear that they were tested numerically with the same rigour as was done by more modern philosophers. Newton deduced from Kepler's laws that the sun exerts an attractive force on the planets varying as the inverse square of the distance. He did not announce his law of universal gravitation, however, until he had demonstrated that the fall of the moon towards the earth in a second was to the fall of a body at the earth's surface in the ratio of inverse squares of the distance from the earth's centre. He also demonstrated that a sphere attracts external bodies as though concentrated at its centre. Hence while we recognise the merits of the ancient philosophers, we cannot put them on the same level as Newton.

Measures of the Brightness of Earth-shine.—Prof. H. N. Russell in the *Scientific American* for July gives an account of the measures of the intensity of earth-shine on the moon made by M. Danjon at Strasbourg. He used an ingenious photometer of his own design in which the light of the sunlit lunar crescent was admitted to one section of the objective, weakened by reflection from plane unsilvered glass surfaces, and then compared with the earth-shine admitted into another section of the objective. He found that when the moon is 30° from the sun the earth-shine is $\frac{1}{1000}$ of the intensity of an equal portion of the sunlit crescent; at 90° from the sun the ratio is less than $\frac{1}{10000}$; at 120° from the sun it is $\frac{1}{40000}$. It cannot be followed further than this. The experiments also showed that the earth-shine was bluer than the reflected sunlight; they indicated that the earth is a less rough reflector than the moon, which is reasonable since much of the earth's light would be that reflected from vapours in its atmosphere. The resulting albedo of the earth is about 29, perfect whiteness being represented by 100. The figure is lower than previous estimates, which have been in the neighbourhood of 50. It is concluded that the full earth would give the moon $\frac{1}{10000}$ of the light of the sun, or more than 40 times as much as the full moon gives us. Allowing for the difference of areas, the albedo of the moon is $\frac{1}{3}$ of that of the earth, or about 10.

Research Items.

The Spirit Cult in Hayti.—The spirit cult of Hayti, ore popularly known as ' voodoo ', is the subject of communication by Dr. Elsie Clews Parsons in the *ournal de la Société des Américanistes de Paris*, .S. t. 20. The spirit cult has hitherto been unde-ribed, owing to the attention given to one of its puted features, namely, ritual cannibalism, the folk-re of which is widespread among foreigners. If uman sacrifices occur or have occurred, it is in con-xion with the ' taureau criminel', the criminal bull, ie of the *loi* or spirits, of which there are a large umber, both Catholic and African. The cult makes distinction between patron saint and West Coast tish, and may be described as the theory and practice possession by spirits. Every *loi* has his or her aits, an appetite for this or that offering ; some like *fia* (rum), others lean to a taste in dress or colour, a rticular day of the week, a particular way of taking ssession, and so forth. For example, *Loi Gédé* talks rough his nose when he takes possession of anyone ; eats only cassaba, pepper and herring ; he is a master the cemetery. *Loi Exili* likes handkerchiefs and ce clothes ; they must be red ; in her food perfume ust be put, and her favours are for men only, and thing for girls ; she is identified with a Catholic int who carres a dagger in the hand. People who t *Loi Coulève* (snake spirit) walk on their bellies. ie snake is small in the day-time but at night it comes so big as to weigh down the branches of trees. visits houses, and people do not kill it. The *loi* may cherished by anyone and may take possession of yone, or it may have been inherited within the mily so far back as the old people who were born in inea. Maintaining the shrine of the *loi* or making oper food offerings are important ways of holding eir favour. The ceremonial cult of the spirit is served in *Mangé loi* and *dansé loi*, spirit feasts and irit dances, in which some, or at times all, partici-nts are possessed. Secrecy attaches to them to a eater or less degree according to the disposition of e local constabulary.

Way-finding of Birds.—The factors concerned in the igration of birds appear to be manifold and not sily disentangled, but it is generally held that the pulse to migration is associated with the develop-ent of the sex organs. One of the most extraordinary cts of annual bird movements, conclusively proved the method of ringing, is the return of spring grants to the locality and even to the exact place which they were born, and the question arises ether this orientation is connected in any way with e development of the sex glands. A problem, allied t not identical, has been tested by G. J. van Oordt d C. J. A. C. Bol (*Biolog. Centralbl.*, Bd. 49, 1929, 173). Carrier-pigeons possess an exceptionally rong ' bump of locality ', and if this power is associ-ed with the sex glands, the influence of castration ould be apparent. The result was negative : the ly conclusion to be drawn from the experiments s that the sex hormones had no influence whatever the way-finding of carrier-pigeons. This result has, course, no bearing upon the origin, the significance, the purpose of bird orientation, but it must be garded as a caution against premature acceptance of e suggestion that sex-hormones play a part in the rection impulse of wild migratory birds.

Aquatic Caterpillars.—H. S. Pruthi (*Records Indian us.*, vol. 30, pt. 3, 1928) describes the aquatic larva d pupa of *Aulacodes peribocalis*. He observed the terpillars in the Nerbudda river in November-December 1927 wherever the water was shallow and the current rapid. They spin their silky shelters, irregular in outline, in the crevices of rough stones. The shelter, which lodges only one caterpillar, is loosely attached to the substratum, leaving numerous openings by which water can enter or leave it, so that there is a free circulation of water round the caterpillar. The caterpillar does not appear normally to leave its shelter, and there seems to be no reason why it should, for there is always around it, within the shelter, an ample supply of fresh water laden with food materials—the larva probably feeds on minute pieces of alga. Its mouth-parts are like those of terrestrial caterpillars. Although the caterpillar is aquatic it cannot swim ; if its shelter is torn away the caterpillar creeps towards the under sides of stones. The caterpillar is provided with eleven pairs of well-developed gills borne by the second and third thoracic and the nine abdominal segments, but it can live for four days after being taken out of the water. Spiracles are present, but their openings appear to be closed and the lumen of the tracheæ connecting them to the lateral tracheal trunks is more or less obliterated. When the larva is full grown, it makes under its shelter a tough and complex dome-shaped cocoon in which the pupal stage is passed. The central cavity of the cocoon communicates with the exterior by a very narrow crescent-shaped slit towards which the head of the pupa points. The moth emerges through this opening.

Brooks's Law.—Robert Gurney (*Internat. Rev. d. ges. Hydrobiol.*, Bd. 21, 1928) has examined a number of growth stages of Copepoda with the view of testing the validity of ' Brooks's Law ' propounded by Fowler (1909) as follows—" during early growth, each stage increases at each moult by a fixed percentage of its length which is approximately constant for the species and sex". Both Fowler, working on marine Ostracoda, and Sewell, on the Copepoda of the Bay of Bengal, found that in some cases there were two adult forms in each sex distinguished by size, and in one case the two forms of the adult male differed also in some structural features so much that they would have been admitted as distinct species if they had been taken separately. The author has investigated fresh-water plankton, in which as a rule only one species of Calanoid occurs, as being more favourable material than marine plankton containing a number of species. He gives details of growth factors in half a dozen species, and his general conclusion is that ' Brooks's Law ' as stated by Fowler cannot be upheld but that the subject is worthy of more attention. Within rather wide limits there probably is a specific growth factor, but there is much individual variation, and the factor changes from moult to moult in most cases. The presence at the same time of large and small forms of the adult, according to the view of Fowler and Sewell an example of dimorphism within a single race, is capable of other explanations. The author finds it difficult to escape any other explanation than that there is a moult in a small proportion of the adults.

Control of the Codling Moth.—We learn from a recent *Daily Science News Bulletin* issued by Science Service, Washington, D.C., that an experiment is under way to attempt the control of the codling moth in the walnut groves of California by biological means. Advantage is being taken of the fecundity of a minute chalcid egg-parasite by adopting mass-rearing and liberation of the latter. The parasite

(*Trichogramma minutum*) is known to attack a great variety of insect eggs, and those of the grain moth have proved well suited for the experiment. It is stated that, in a building with a floor space of only 25 ft. × 36 ft., it is now possible to rear one million *Trichogramma* per day, the whole technique being a matter of skilful standardised routine. Packages containing 100,000 parasitised eggs of the grain moth occupy a very small space, and are easily sent by mail to growers troubled with codling moth. The parasites which emerge from these eggs are liberated in the walnut groves, and soon commence seeking out codling moth eggs, which are at hand in abundance. It is hoped that by materially raising the *Trichogramma* population in given districts, wholesale destruction of codling moth eggs will result, with a consequent reduction of the injuries wrought by this insect.

Light Periodicity and Plant Growth.—A further study of the importance of light duration as a factor in plant growth has been made by G. Reddington (*Trans. Roy. Soc. Edin.*, **56**, 247-272; 1929), using throughout specified conditions of electric lighting. A large number of species of plants were examined and all, except beech seedlings, grew *initially* best in continuous light but *finally* best in 16 or 8 hours of light per day. The results are explained on the supposition that carbohydrate supply is primarily the limiting factor in growth, but that, where continuous light is used, water strain may, in the later stages, limit food and water supply to the growing points. Detailed observations are given in support of this argument.

Movements of Liquids and Gases in Trees.—The problem of the ascent of water in trees is being re-examined by D. T. MacDougall, J. B. Overton, and G. M. Smith, and they have recently reported (*Carnegie Instit. Wash.*, No. 397; 1929) data as to the movements of water and gases in various trees. They find great differences in the paths of movement of dye solutions injected or allowed to enter into woody stems. In some species these only move along the summer wood, in some only along the spring wood, and in others along the late autumn and early spring wood. In Monterey pine, however, the dye travels along the whole of each annual ring of wood. The evidence suggests that the non-conducting vessels are full of gas. Examination of the internal gas pressures shows them to be subject to considerable seasonal variations. Applying suction to the gas in the tree increases the tensions on adjacent water-filled manometers, but if gas pressures (of 4 atmospheres) are applied, they are registered by air manometers 2 m.-3 m. higher up the tree but not by water-filled manometers. It is therefore concluded that varying internal gas pressures have little effect on the cohesive water system.

Miocene Mollusca of Virginia and North Carolina.—Mr. W. C. Mansfield in a short paper (*Proc. U.S. Nat. Mus.*, vol. 74, art. 14) briefly outlines the different divisions of the Chesapeake group of the Miocene epoch in Virginia, and describes and illustrates on wonderfully clear plates, seven new species and five new sub-species of mollusca therefrom. We are promised further and more complete discussion of the whole in a forthcoming number of the George Washington University *Bulletin*.

Height of Mount Everest.—A note on this subject appears in the General Report of the Survey of India for 1927–28. The value of 29,002 ft. was computed in 1852 from observations taken in 1849–50. The last figure is retained, not on account of its probable accuracy, but in order to avoid the suggestion of an estimate in round figures. In 1907, Sir Sidney Burrard calculated the height to be 29,141 ft. Dr. de Graaff Hunter, applying improved refraction corrections to results from different observation stations, gets a height of 29,149 ft., which has a probable error of less than 5 ft. and a possible error of less than 15 ft. This, however, is more than the true geoidal height. When the correction is applied, Mount Everest has a probable height of 29,075 ft., with a possible correction of 25 ft. either way. It is impossible at present to give the height of Mount Everest with greater accuracy.

The Upper Atmosphere.—In the issue of the *Physikalische Zeitschrift* for Mar. 1, Prof. H. Benndorf, of the University of Graz, gives an account of the methods which have been used recently to obtain a more precise knowledge of the properties of the upper atmosphere. Altitudes of 20 km. to 30 km. have been attained by pilot balloons with registering instruments, but for greater altitudes the study of the propagation of sound waves through the atmosphere has given the most trustworthy data. Prof. Benndorf considers our present knowledge justifies the following statements. Traces of atmospheric gases can be detected at altitudes of 1000 kilometres, and at such altitudes motions of these gases must be rapidly damped down owing to their high kinematical viscosity. In the northern hemisphere there is a drift of the layers between 30 km. and 80 km. altitude to the east and above that to the west. In the 'troposphere' up to 12 kilometres convection currents keep the atmosphere well mixed and the temperature decreases with altitude until 220° absolute is reached. In the 'stratosphere' above, convection is less marked and the temperature remains constant at 220° up to 30 kilometres. Between 40 km. and 60 km. a layer at about 300° absolute—a tropical temperature—exists. For greater heights no statement can be made, nor is the composition there known, but there is no doubt that the gases there are ionised, that the negative ions are electrons, and that at altitudes of 80 km. to 100 km. there exists at least one conducting layer with free electrons numbering 10^5 per c.c.

An Optical Law for Electrons.—The existence of still another analogy between electrons and waves has been indicated by E. Rupp in a recent issue (May 17) of *Die Naturwissenschaften*. When slow electrons impinge on a very thin sheet of metal, those which are not retarded are transmitted selectively, silver, for example, being very approximately two and a half times as opaque to electrons with an energy equivalent to 11 volts as it is to 16-volt electrons or 8-volt electrons. It is now found that the same selectivity is exhibited in reflection of electrons without loss of energy, silver again reflecting electrons particularly well when their energy is close to 11 electron-volts, and it would thus appear that the optical law connecting absorption and reflection is valid for electron waves. No relation has yet been traced between the wave-lengths of the electrons and the atomic constants of the metal foils, but it is suggested that absorption and reflection of the slow electrons are occasioned by the outer dispersion electrons of the metallic atoms.

Melting-point of Palladium.—A determination of the melting-point of palladium by Hoffman and Meissner in 1919 resulted in a value of 1556° C.

hich is 3° above the previously accepted tempera-re, and it is therefore interesting to note that a re-termination is described by Fairchild, Hoover, and ters in the May issue of the *Journal of Research*, pub-hed by the U.S. Bureau of Standards. The method nployed consisted in measuring the relative bright-ss of black bodies at the melting-points of gold and lladium, and calculating the upper temperature means of Wien's law, which is equivalent to anck's law for light and gives the spectral distribution radiation from a black body. The melting-point gold was taken as 1063°. The result obtained as $1553{\cdot}6 \pm 0{\cdot}5°$ C., and when all possible sources error are considered, the melting-point of pure lladium is probably $1553 \pm 2°$.

Dielectric Constant of Desiccated Oxygen.—The ange in the chemical activity of oxygen produced prolonged drying is accompanied by an increase the dielectric strength of the gas. Thus a greater otential is required to cause an electric spark to ss through the dry gas than through ordinary ygen. An investigation to determine whether this ange in properties involves a modification of the ructure of the oxygen molecule with a consequent ange in the specific inductive capacity, is described Riley in the *Journal of the Chemical Society* for ay. The method used was to compare the capacities two similar condensers of the same dimensions, one ntaining carefully dried oxygen and phosphorus ntoxide, and the other oxygen passed over calcium loride. By means of a thermionic valve apparatus e condensers were found to have the same capacity, d no change could be detected after ten months' posure of the gas to phosphorus pentoxide. Hence, e chemical activity promoted by the presence of nall traces of water does not appear to be connected ith any change in molecular structure.

Magnetic Storms and Radio Signals.—A recent *Daily cience News Bulletin*, issued by Science Service, ashington, D.C., reports that at a meeting of the merican Geophysical Union on April 23, Miss I. J. ymore announced that the Radio Laboratory De-artment of the Bureau of Standards has discovered interesting relation connecting magnetic storms and dio signals. When the radio signals from European ations are weaker than usual and the signals from arer stations in America are louder, then magnetic orms may be expected. After a magnetic storm uch stronger signals are received from distant ations. The conclusions were deduced from the cords obtained by experiments made with the long aves used for high power trans-oceanic transmission. veral days before the maximum of the terrestrial agnetic disturbance the signals were weak when ceived at Washington. The trans-oceanic signals, owever, received at Washington from Tuckerton, ew Brunswick, N.J., and Rocky Point, L.I., were cidedly stronger at periods varying from two to ur days before the magnetic disturbance.

Composition of Gum Arabic.—There are a number substances, such as pectins, plant gums, hemicellu-ses and mucilages, which appear to be formed by e influence of enzymes upon cellulose and may be rmed acid polysaccharides. Comparatively little is own concerning the structure of these substances, d an account of an investigation of the composition gum arabic in the May issue of the *Journal of the merican Chemical Society* is therefore of considerable terest. The plant gums are usually the calcium, agnesium, and potassium salts of very complex rganic acids, and arabic acid, obtained from gum rabic by hydrolysis, appears to be an aldobionic acid of formula $(C_{12}O_{20}H_{12})_n$. Among the products of further hydrolysis, rhamnose, *d*-galactose, *l*-arabinose, and *d*-glucuronic acid have been identified.

Synthesis of Chaulmoogric Acid from Hydnocarpic Acid.—Chaulmoogric and hydnocarpic acids are constituents of chaulmoogra oil, and are of great importance on account of their extensive use in leprosy therapy. Some years ago Power concluded that chaulmoogric acid is a homologue of hydnocarpic acid, and this has recently been confirmed by Stanley and Adams. They have synthesised chaulmoogric acid from hydnocarpic acid by successive conversion of the latter into the ethyl ester, the alcohol, bromide, and through hydnocarpylmalonic acid to hydnocarpylacetic acid. The latter showed no depression of the melting-point (68°) when mixed with pure natural chaulmoogric acid and had a rotation of $+61{\cdot}9°$. The amides prepared from the synthetic and natural products also had identical melting-points. This work is described in the *Journal of the American Chemical Society* for May, which also contains a paper by Hinegardner and Johnson on the preparation of chaulmoogrylresorcinol and some of its derivatives. The bactericidal properties of these compounds are being examined in the hope that they may be free from certain objectionable effects produced by prolonged use of chaulmoogric acids.

Long Period Forecasting.—A reprint has been received of a paper by E. T. Quayle on "Long Range Rainfall Forecasting from Tropical (Darwin) Air Pressures", which appeared originally last year in the *Proceedings of the Royal Society of Victoria*. The economic importance of this subject for a country with a rainfall so capricious as that of Australia is evident, and the results obtained are such as to suggest that the accuracy of forecasts of the early spring rainfall of Northern Victoria, based purely on Darwin pressure for the two winter months of June and July, renders these of genuine value. The relationship is a negative one, low tropical pressure being followed more than eight times out of ten by rainfall above the average, and it seems highly significant that the connexion is actually closer than that between synchronous pressure and rainfall for two-month periods. The relationship diminishes quickly when earlier or later periods are considered; thus between Darwin pressure for June and July and the rainfall of ten representative stations in Northern Victoria in August and September, the correlation coefficient is $-0{\cdot}79 \pm 0{\cdot}04$, while between May and June pressure and July and August rainfall the coefficient is only $-0{\cdot}65 \pm 0{\cdot}06$. For July-August pressure and September-October rainfall the coefficient is even smaller, namely $-0{\cdot}52 \pm 0{\cdot}07$. This detracts less from the value of the results than would be the case were the spring rainfall not of such particular importance in cereal production, and for the growth of the pasture. The relationship, it may be noted, is of the simple linear kind which justifies the use of the ordinary regression equation in the calculation of rainfalls for individual seasons, and offers some prospect of good results in the anticipation of the dreaded droughts. Presumably the clue to this relationship is to be found in the southward migration of the tropical low-pressure belt with the approach of the Australian summer, and it seems to imply a greater continuity in any abnormal feature of this belt than might have been expected. This aspect of the matter, interesting as it is from the theoretical side and from the possibility it holds out of unravelling the physical processes at work in the production of abnormal seasons, the author unfortunately does not follow up.

Annual Meeting of the Royal Society of Canada.

THIS meeting was held in Ottawa on May 20-22, in the Chateau Laurier. The president, Mgr. Camille Roy, Rector of Laval University, Quebec, addressed the Society on "Provincialisme intellectuel au Canada". Prof. J. C. Chamberlain, of Columbia University, gave, by invitation, the popular evening lecture on "The United States Government and International Relations". At the annual luncheon of the Society, brief addresses were given by Sir Robert Borden, the Hon. Wm. Phillips, United States Minister to Canada, the Hon. Jean Knight, Minister from France to Canada, and Sir Wm. H. Clark, British High Commissioner.

Prior to the delivery of the presidential address, the following gold medals were presented: The Flavelle Medal (science) to Prof. A. H. R. Buller, of the University of Manitoba, immediate past president, for his work on Fungi; the Lorne Pierce Medal (literature) to Mgr. Camille Roy, for his contributions to French-Canadian literature; and the Tyrrell Medal (Canadian history) to Prof. George M. Wrong, of the University of Toronto.

Thirty-one papers on historical and literary subjects were communicated in Sections I and II (French and English Literature and History).

Among the 150 papers communicated to the three scientific sections the following may be noted:

In Section III (Physics, Mathematics, Astronomy, and Chemistry) the sectional presidential address was given by Prof. Frank Allen, of the University of Manitoba, and was a summary of his twenty years' investigation of the laws underlying the response of the human nervous system to various types of stimuli. He has shown that a logarithmic law holds for such sensations as vision, taste, touch, and hearing, when the relation between intensity and frequency is measured. Weber's law has now been proved to hold for mechanical stimuli. The action of the nervous system is fundamentally the same for all types of stimuli. As a result of this series of researches, many psychological tests can now be placed on a true quantitative basis.

Drs. J. S. Plaskett and J. A. Pearce, in a paper on the rotation of the galaxy, conclude from analysis of 500 radial velocities of *B* type stars that the galactic system revolves in its own plane in a period of more than 10^8 years about a centre in the direction of Sagittarius some 30,000 light years away. Dr. C. T. Sullivan presented a simplified proof of an auxiliary theorem used in Bescovitch's solution of Kakeya's minimal problem. Dr. L. L. Dines dealt with the resultant of two power series in two variables. Drs. A. S. Eve, L. V. King, and L. Gilchrist presented papers on the practical and theoretical results of estimating the depths of an ore-body by electrical means in geophysical investigations. Dr. J. S. Foster dealt with results obtained in the study of the Stark effect in parallel and crossed magnetic and electric fields in helium. Prof. J. C. McLennan presented a large number of papers by himself and his associates on various spectroscopic investigations. The papers on the Raman effect in liquid hydrogen, liquid oxygen, and liquid nitrogen were of particular interest in that they confirmed the correctness of Dennison's view that hydrogen at low temperatures consists of two effectively distinct sets of molecules, symmetrical and anti-symmetrical.

Dr. E. F. Burton demonstrated a new and important method of measuring the moisture content in grains, woods, and tobacco. The device used is a critically adjusted oscillating system extremely sensitive to changes in conductivity caused by the presence of moisture in the materials investigated. Dr. J. A. Gray, speaking on cosmic rays, deduced from experimental results and theoretical considerations that it is not possible to account for the most penetrating type of the penetrating radiation on any hypothesis of the synthesis of atoms from protons and electrons.

Dr. O. Maass and his associates gave papers on hydrogen peroxide as an oxidising agent and as a solvent, on the liquid state as a catalyst, on the viscosity of carbon dioxide at low temperatures, and on absorption and diffusion of vapours through wood. Dr. G. S. Whitby and his collaborators dealt with colour reactions of caoutchouc and other unsaturated hydrocarbons, on polyindenes, and on various related subjects. Dr. R. H. Clark dealt with the preparation of alkyl chlorides from the corresponding alcohols, and with the oxidation of aromatic amino-groups. Drs. M. C. Boswell and R. C. McLaughlin gave the results of an investigation which suggests that the mechanism of the Deacon process is more complex than has been usually held.

In Section IV (Geology and Allied Subjects), Dr. R. C. Wallace, president of the University of Alberta, in his sectional presidential address, dealt with the educational aspects of the group of sciences covered by the section, and in particular with the place of geography in a university course. Physiographical papers were presented on the deepening of Burrard Inlet, B.C. (W. A. Johnston), the relationship of the St. Lawrence fault to the Palæozoic margin (Carl Fissler), and the mature valleys of the Labrador peninsula (H. C. Cooke). Palæontological contributions included the history of deposition in Canada in Silurian times (M. Y. Williams), an account of two new theropods from the Belly River dinosaur beds (C. M. Sternberg), and the faunas of the Triassic in the Upper Peace River area (F. H. McLearn). Studies in sedimentation were dealt with by E. M. Kindle (the inter-tidal zone of the Wash, England), and F. J. Fraser (the character of some heavy minerals in Canadian sediments). C. W. Knight presented evidence determining the age of the Nipissing diabase as pre-Cambrian. Other papers included the physiography and geology of Great Slave Lake (J. M. Bell), a new type of fibrous magnetite, and the characteristics of the olivine diabases of Keeweenawa age in the Canadian Shield (E. M. Moore), and a chemical study of the Sudbury intrusive, as evidence of differentiation in a single eruptive (T. L. Walker).

The presidential address in Section V (Biological and Medical Sciences) was given by Prof. F. J. Lewis, of the University of Alberta. Dealing with the broader aspects of plant ecology, he pointed out the importance of past investigations in New Zealand, Australia, and South Africa on various types of grasslands and the effects of burning and grazing upon them to a country like Canada in which grazing is a prominent feature of farming, and considered that study of soil moisture and soil aeration, especially as regards their effects on germination and the development of seedlings, is likely to explain much of the existing distribution of different types of vegetation. The remarkable parallelism between different types of woodland and grassland is of considerable economic importance, since grasses in an area may indicate the species and types of woodland for which that locality is most suitable and thus facilitate afforestation.

Prof. A. H. R. Buller, by employing the Barger capillary tube method, has shown that the osmotic

essure of the cell sap of *Pilobolus* is about 5·5, and he d T. C. Vanterpool reported that the so-called condary conidia of the stinking smut fungus are ie basidiospores. Dr. W. P. Thompson and collarators gave a series of important papers dealing with e cytological cause and genetical effects of shrivelled dosperm in species-crosses of wheat, chromosome mologues in wheat and *Ægilops*, and chromosome fferences in the *vulgare* wheats.

Other papers included craniometrical studies inlving a number of new cranial indices (John meron), data concerning the numbers of molecules the red-blood corpuscle (A. T. Cameron), study of ostate extracts with an adrenine-like action (J. B. Collip), new evidence as to the true location of the respiratory centre, in disagreement with Lumsden's work (V. E. Henderson and T. A. Sweet), forelimb reflexes and their reciprocal muscular co-ordination (F. R. Miller), and the temperature limits of *Grylloblatta* (E. M. Walker). Dr. F. C. Harrison gave an important communication on the cause of discoloration of the bellies of Pacific Coast halibut, which he showed to be due to *Ps. fluorescens* introduced by the ice used for packing the fish.

The meeting in 1930 will be held at McGill University, Montreal, under the presidency of Prof. A. S. Eve, Macdonald professor of physics in McGill University.

Afforestation of Peat Lands in Sweden.

FOR a considerable period the Swedish Institute of Experimental Forestry has devoted extensive search to the problem of draining peat and marshy nds for afforestation purposes. Numerous investitions have been carried out with the view of gaining creased knowledge of the various properties of peat il types and their suitability to draining by the dinary forest method of open ditches. The importce of this study to Sweden will be evident when it remembered that half the total exports consist of e produce from her forests, and that it is estimated at there are some 3,000,000 acres of this type of nd which can be made suitable for the growth of ees.

The methods of inquiry projected have been on veral different lines. Earlier types of drainage tches have been studied with their results; and ecial drainage operations have been undertaken on rying types of marsh and peat lands, which have en thoroughly investigated geologically, hydrogically, and biologically. Laboratory investigations ve also been undertaken into the physical and emical properties of various kinds of peat. The reful work thus carried out over a series of years ay have some considerable importance to Great itain, in parts of which extensive tracts of peat nds exist.

The results of the Swedish investigations have been blished in the *Reports of the Swedish Institute of xperimental Forestry*, No. 24 (1927–28), the paper by rl Malmström being entitled "Våra Torvmarker ur ogsdikningssynpunkt". The author states that s paper gives a general review of the results that ve been obtained in regard to the suitability of fferent types of peat ground for draining, both as the possibilities of draining it with advantage d the qualities of the timber to be obtained from it ter the operations.

Investigations into the possibility of extending the ea of forests in Sweden were begun in the middle of st century, coinciding with the commencement of veden's exploitation of the forests to capture a share the European trade in soft woods which were replacg the broad-leaved timbers. Amongst others, C. G. debetow, T. L. Bohnstedt, and Bishop C. A. Agardh vocated ditching as the method by which poor un oductive peat lands might be afforested; the latter ating that the removal of excess water by this eans would also improve the local climate.

Towards the end of the nineteenth century, a ther motive for carrying out this type of drainage eration arose, it being suggested that such drainage uld prevent peat-formations from spreading over ll healthy forest land. At the beginning of the esent century, therefore, the inquiry was considered from the twofold point of view of improving boggy land and as a protective measure, in many cases considered essential to obtain enduring results from good forest lands. The protective idea originated in northern Sweden, where there are extensive areas of poor forest growth where the soil is covered entirely or in patches with carpets of *Sphagnum* and *Polytrichum commune*. The fear of the spread of this type of formation came to be applied to parts of southern and central Sweden, and particularly to areas, as for example in western Småland and north-west Dalecarlia, where widespread complexes of moss are to be found. The investigations by the Institute of Experimental Forestry so far carried out, in this latter direction, are said to have produced "incontestable evidence that at the present time the danger of any general process of rapid bog-formation affecting the forests of Sweden is slight". The caution is added, however, that "this does not mean that locally, *e.g.* in the case of neglecting to clean out ditches, the confluence of streams, deforestation, forest fires, etc., processes of bog-formation cannot take place comparatively rapidly".

The business of improving poor peaty and marshy land in Sweden by laying out a series of ditches has now many enthusiastic adherents, both government and private land owners, and the author deems it necessary, owing to failures which have been experienced, to voice some warnings. Difficulties, he says, very similar to those experienced by farmers when they have sought to utilise certain types of peat land for cultivation purposes, have been experienced by foresters. Just as the farmer learnt by sad experience that it is wasted labour to try to cultivate economically, for example, mosses with large superficial layers of entirely undisintegrated *Sphagnum* peat, the forester now realises that certain types of peat soil react extremely slowly, if at all, after draining; whilst others soon after draining show a considerable and enduring improvement in the forest growth.

On the subject of the amount of water to be drained off, it has been shown that varying types of peat soils display remarkable differences in this respect. Investigation work has accordingly been concentrated on the degree of moisture and the biological properties of peat ground and also on its productive capacity after draining from the forestry point of view, and it is hoped by this means to arrive at an even greater certainty in the selection of areas to be drained and also on the correct method of laying out the system of drains for particular types of peat and marshy areas. The necessity for protective drainage schemes having, as explained above, been proved to be of local importance only, the investigation work is now

concentrated on drainage for afforestation purposes and the work is confined to those classes of peat soil which have so far been shown to respond and to show, without too expensive and elaborate a drainage scheme, a considerable and lasting improvement within a short time. "Peat ground", says the author, "that is hard to drain off and poor in quality, or in which the reaction takes place too slowly, must obviously, according to the present views, be entirely abandoned. It is clear, however, that in the event of drainage operations becoming cheaper or forest products increasing in value, or should it be possible to reduce the administrative and transport costs of lumbering, the poorer types of peat ground may be advantageously treated." The author then deals at length with the drainage possibilities of peat ground, its qualifications for producing timber after draining, and finally considers the conditions governing the most important types of peat land where draining is to be undertaken.

On the subject of classifying peat ground for forestry purposes, Mr. Malmström says that experience has shown that it is not possible unreservedly to use the old schemes of differentiating the types, which were set up on the basis of the topography, the plant associations, or the evolutionary history of the peat ground. Some of these may usually be better than others, but exceptions to this rule have been found. Unfortunately, there is at present no possibility of forming any such judgment in a simple stereotyped way, such as with the guidance of a certain definitely determinable property in the virgin peat soil. The peat's power to react after draining is determined by many contributory factors; as, for example, the composition of the peat, degree of disintegration and porosity, fungal and bacterial life, climate, and, above all, the power of the peat to absorb and retain water.

There is, however, an empirical and, for practical purposes, satisfactory method of judging in advance the qualifications of peat ground for producing timber after draining. This consists in studying the vegetation produced on the peat in its natural state and taking special note of the presence or absence of certain plants. Luxuriant vegetation (especially dwarf shrubs and bushes) often provides a good indication as to the biological conditions of the ground; that is, of those intrinsic properties which, after draining, largely determine the success of forest production, although they are not apparent from direct observation of the plant community. The species of trees and certain bushes and shrubs are particularly helpful. Alder (*A. glutinosa* and *incana*) is a good indication on several types of peat; and spruce and birch may also serve as a sign, especially if the trees have a healthy and normal appearance. The spruce by itself is more uncertain, and where it is stunted and knotty usually indicates a soil unsuitable for drainage schemes. Willows, juniper, and dwarf birch (*B. nana*), if tall and flourishing, indicate peat soils worth draining. When the areas are treeless, experience has shown that the presence of certain grasses, sedges, and herbs will furnish an indication of the peat's disintegration and porosity, especially in south and central Sweden. Plants of this kind are high sedges (*Carices*) and various types of cotton grass (*Eriophorum*): when these are present and the peat is fairly well disintegrated, the area is suitable, whilst the reverse is the case with areas of more or less undisintegrated peat covered with cotton grass and *Scirpus cæspitosus*.

Mr. Malmström's paper may be regarded as a valuable aid in a most important and difficult problem in afforestation in which forest officers in several parts of Europe are vitally interested, and it will well repay a careful study.

University and Educational Intelligence.

BIRMINGHAM.—The Walter Myers travelling studentship for research in any branch of pathology approved by the selection committee is being offered. The value is £300. The holder of the studentship will be required to devote his or her whole time to research. Applications must reach the Dean by at latest Sept. 2.

EDINBURGH.—At the summer Graduation Ceremonial the honorary degree of Doctor of Laws was conferred upon Mr. J. B. Clark, formerly Headmaster of George Heriot's School, Edinburgh; Prof. E. S. Goodrich, Linacre professor of zoology and comparative anatomy, University of Oxford; Prof. A. V. Hill, Foulerton research professor of the Royal Society; Prof. C. E. Inglis, professor of mechanism and applied mechanics, University of Cambridge; Dr. A. P. Laurie, formerly principal of the Heriot-Watt College, Edinburgh; Sir James Walker, professor-emeritus of chemistry; and the Right Hon. Lord Woolavington of Lavington. The degree of Doctor of Science was conferred on Mr. John Mackie, for a thesis entitled "An Inquiry into the Tetrad-difference Method of Testing the Two-factor Theory of Intelligence"; Dr. Christina C. Miller, for a thesis entitled "The Slow Oxidation of Phosphorus"; Dr. Frederick Walker, for a thesis entitled "The Geology of the Shiant Isles"; and Mr. John M. Whittaker, for a thesis entitled "On the Stieltjes Integral and on the Expansions of Interpolation Theory".

The Court has appointed Mr. C. B. Williams to be Steven lecturer in agricultural and forest zoology in succession to Dr. Stewart MacDougall.

MANCHESTER.—Invitations are invited for the Amy Henrietta Worswick Fellowship, value £150, for the investigation of the causes and treatment of rheumatoid arthritis. Applications must reach the Registrar by Oct. 15.

ST. ANDREWS.—By a recent ordinance a chair of botany has been established in the University, placing under the new professor the Departments of Botany in the United College, St. Andrews, and in University College, Dundee. The lectureship in botany in Dundee and the assistant lectureship in the United College as presently existing are continued under the new arrangement, and it has been agreed that the first appointment to the new chair should be offered to Mr. R. A. Robertson, who was appointed lecturer in botany in the United College, St. Andrews, in 1891, and reader in botany in 1915. Mr. Robertson has accepted the offer and has been appointed as from Oct. 1 next.

THE Trustees of the Beit Fellowships for Scientific Research have made the following elections to fellowships tenable at the Imperial College of Science and Technology for two years 1929–30 and 1930–31, of the value of £250 per annum: Mr. N. S. Grace, University of Saskatchewan, Saskatoon, Canada, for physical chemistry; Mr. J. J. Green, Imperial College, for an investigation of the nature and cause of the breakdown in agreement between the theoretical and observed viscous fluid motion round a circular cylinder; Dr. F. K. V. Koch, Imperial College and Universities of Dresden and Munich, for the continuation of an inquiry into the solution tension of silver in solvents other than water, and the connexion between solution tension and complex formation. The Trustees have confirmed the awards for a second year to Mr. A. A. Fitch (geology); Mr. J. M. Frankland (metallurgy); Mr. E. C. S. Megaw (electrical engineering).

Calendar of Patent Records.

July 23, 1888.—J. B. Dunlop's patent for the pneumatic tyre is dated July 23, 1888. Though his invention had been anticipated in the year in which he was born, more than forty years earlier, by R. W. Thomson, the popularity of the bicycle at the later date provided a rapidly growing market for the new tyre, and it is on Dunlop's work and enterprise that the present industry is based.

July 24, 1874.—The game of lawn-tennis was gradually developed from the older games, tennis, rackets, and badminton, and its actual beginnings are hard to determine, but the first to formulate and codify definite rules and a lay-out for the court was Major W. C. Wingfield, who patented his game on July 24, 1874, under the name of 'Sphairistiké'. Wingfield's court was narrower at the net than at the serving lines, and this form was adopted by the M.C.C. committee when it published its rules in 1875, but the rectangular court with practically the present dimensions was general by 1877. The cloth-covered ball is due to John Heathcoat, the tennis-player.

July 25, 1698.—The first steam engine successfully to operate—for pumping water out of mines, one of the great problems of the day—was the invention of Thomas Savory, who was granted a patent on July 25, 1698, and published an account of the invention in 1702 in his book "The Miners' Friend". The life of the patent was extended for 21 years by Act of Parliament in 1699.

July 26, 1588.—Modern shorthand dates from the patent granted on July 26, 1588, for 15 years, to Dr. Timothy Bright, resident physician at St. Bartholomew's Hospital, which licensed him "to teache, imprynte, and publishe, or cause to be taughte, imprynted, and published, in or by character not before this time commonlye knowne and used by any other oure subjectes". In the same year Bright published a description of the system in his book "Characterie. An arte of shorte swifte and secrete writing by character". A specimen, dated 1586, is in the Lansdowne MSS. in a communication to Sir Robert Cecil.

July 26, 1810.—J. C. Dyer's patent for a nail-making machine, dated July 26, 1810, is an important landmark in the history of the nail industry. There was considerable difficulty in getting the machine adopted, but finally a company was formed in London to work the invention and works were opened. By 1817, the machine-made nails had become a serious competitor in the market, as is evidenced by a petition to the House of Commons, which, referring especially to Dyer's factory, directed attention to "the ruin of the trade and devastation of the country" that was being brought about by the new industry.

July 26, 1811.—A patent was granted on July 26, 1811, to Henry James and John Jones for a method of welding gun-barrels by means of a series of hammers and for a lathe for turning barrels instead of grinding them. Jones was later employed by the Russian Government in the State Arsenal, where he re-designed all the machinery and organised the factory on the 'interchangeable' system.

July 26, 1907.—The Garratt articulated locomotive, which provides a very flexible engine and allows of a wide increase in the steam-generating capacity within the limits imposed by the width of the track and the loading gauge, was invented by H. W. Garratt, of London, and patented by him on July 26, 1907. The first engine of the type was made by Beyer, Peacock, and Co., in 1909, for the Tasmanian Government Railways, and the development has since been continuous and rapid.

Societies and Academies.

LONDON.

Geological Society, June 12.—E. Mackenzie Taylor: Base exchange and its bearing on the formation of coal and petroleum. The discovery of a bed of vegetable débris containing both peat and fusain under a layer of alkaline soil in Egypt led to the investigation of the effects of the presence of sodium-clay upon the decomposition of organic matter by bacteria. The alkaline soil was shown to be a sodium-clay produced by base exchange between the clay and solutions of sodium chloride. As the result of hydrolysis, a continuously alkaline medium under anaerobic conditions was produced in which continuous bacterial action is possible as the acidic products of such action do not accumulate. Lignocellulose decomposes under these conditions, yielding a material with fusain properties. The decomposition of proteins and fats takes place in the alkaline medium, and, in addition, it has been found possible to decompose free organic acids by bacteria under these conditions. It was suggested that coal and petroleum have both resulted from the decomposition of organic matter by bacteria, under the alkaline anaerobic conditions provided by strata which have undergone base exchange with solutions of sodium salts and subsequent hydrolysis in fresh water. The conditions provided by such strata are favourable to continuous bacterial action, to the elimination of oxygen from the material, and to the accumulation of the decomposition products as the result of the sealing of the organic deposit.

Physical Society, June 28.—Teresa J. Dillon: The relation between hydrogen pressure and filament resistance in a tube containing glowing tungsten. When a tungsten filament in a tube containing hydrogen is caused to glow, the gas rapidly disappears while the resistance of the filament rises progressively. The latter phenomenon can be used to measure the pressure of the hydrogen. Chemical action probably takes place between the hydrogen and tungsten.—Francis Lowater: The band systems of titanium oxide. The bands extend toward the infra-red through some 800 A. farther than the range previously known. Bands in the orange, red and infra-red regions have been analysed into two systems, distinct from the blue-green system, one of these being due to the transition $^1\Pi \rightarrow {}^1\Sigma$, the other to $^3\Sigma \rightarrow \Pi^3$, the latter having the same final energy level as the blue-green system $^3\Pi \rightarrow \Pi^3$.—F. D. Smith: The absolute measurement of sound intensity. The sound is received with a moving coil receiver. The signal heard after suitable amplification is compared with the signal produced by a small known electromotive force applied to the receiver. When the two signals are equal in intensity a simple relation connects the total sound pressure on the receiver with the electromotive force. The phase of the sound can be determined with the aid of a phase-shifting transformer. Since the measurement is independent of the amplifying circuit, it is possible to use a high degree of amplification and very feeble sounds may therefore be measured.

LEEDS.

Philosophical Society, June 17.—R. Stoneley: Love waves of short wave-length. The calculation of the velocity of propagation of transverse surface waves involves a knowledge of the rigidity and density of the medium at all depths. The velocity of very short waves, however, is determined mainly by the properties of the layers near the surface; an asymptotic formula for such waves is developed which depends

on the surface values of the rigidity and density and of their gradients.—**A. O. Allen**: A simplified derivation of v. Seidel's aberration formulæ (2).—**E. C. Stoner**: Diamagnetism and space charge distribution. The diamagnetic susceptibilities corresponding to the space charge distributions obtained by the Hartree self-consistent field method are calculated for He, Li^+, Na^+, K^+, Rb^+, and Cl^-. Except for Cl^-, there is very satisfactory agreement with experiment.—**R. Whiddington**: (1) Some new discharge tube phenomena. Experiments are described using a straight argon-filled discharge tube showing moving striations. There are at least four types of moving striations from flashes possible at one pressure, the type produced depending on the current employed. The change from one type to another is accompanied by an unstable system which is described but not explained. With a steady source of potential applied to the tube, the majority of the current is steady, but superposed on this steady current is a slight flicker amounting to a small percentage only of this whole current. Oscillograph measurements of this flicker show interesting variations of wave form with change of total current. These changes again are described but not explained. (2) A note on the use of the cathode ray oscillograph. A cathode ray oscillograph is often used for indicating the wave form of alternating currents by the associated use of a winking Osglim lamp. The winking frequency and the alternating current frequency must bear some simple integral ratio for this method to be applicable. For certain experiments it was found desirable to superpose a time mark of 50,000 frequency on that of the Osglim lamp so that the trace corresponding to the alternating wave would be segmented at equal time intervals, presenting an appearance somewhat like that of a string of beads. A method of carrying this out is described in which an oscillating valve circuit of about the desired frequency is suitably linked to the lamp, the frequency ratio of the two being again some simple multiple.—**R. Gane**: Carbohydrate content of detached partially shaded leaves. Sucrose and reducing substances are estimated in the distal, median and proximal portions of leaves isolated from the plant; the median portions had been shaded, whilst the rest of the leaf had been exposed to light. Certain differences in the sugar content then found in the leaf seem to be associated with the shading, but the differences do not seem adequate to explain the complete failure of starch to appear in the shaded strip. The distribution of sugars in plantain leaves thus treated, and in those in which the main veins had been removed, suggests that sugars can still move into the shaded region from illuminated ones, in spite of the dislocation of the vein system.—**W. Garstang**: On the dextricolic condition in Tunicates. The author republishes two figures from Barrois which establish the dextricolic condition of *Anchinia* buds, recently disputed by Van Wijhe. Their 'neural cord' is a 'neurogenital cord', comparable with that of *Aplidium* (Brien), but lying in a dextral, instead of a sinistral loop of the gut,—a complete *situs inversus*. The key to this condition is sought in the origin of salps and doliolids from colonial (pyrosomatoid) ancestors, and in the part played by subsequent rearrangements of the gut in balancing the body of free zooids for a locomotive career.

PARIS.

Academy of Sciences, June 10.—The president announced the death of M. Georges Lecointe, *correspondant* of the Academy for the Section of Geography and Navigation.—**Maurice Hamy**: A particular case of diffraction of the solar images at the focus of a telescope. It has been shown in earlier communications that the problem requires the calculation of some very complex double integrals. The evaluation of one of these integrals is dealt with in the present paper.—**Charles Moureu, Charles Dufraisse, and Léon Enderlin**: Researches on rubrene. A new oxide of rubrene. It is known that rubrene can fix a molecule of oxygen giving the oxide RO_2, readily dissociable into rubrene and oxygen. The preparation of another oxide, RO, is now described. This is more stable, is not dissociable into its constituents, but can be reduced to rubrene with ordinary reducing agents. It cannot be converted into the oxide RO_2. There is a close analogy between rubrene, the oxides RO_2, and RO and hæmoglobin, oxyhæmoglobin and methæmoglobin. It is concluded that the characteristic properties of hæmoglobin are not necessarily due to the presence of an atom of iron.—**V. Grignard and Tchéoufaki**: New researches on the additive properties of the α-diacetylene hydrocarbons. Experiments on the products formed by the addition of bromine, hydrobromic acid, and hydrogen to these diacetylene derivatives.—**Jules Drach** was elected a member of the Section of Mechanics in the place of the late J. Boussinesq.—**A. Gelfond**: Picard's theorem.—**Josef Mikuláš Mohr**: The absolute velocity of the sun.—**P. Salet**: The constancy of the velocity of light.—**Holweck and Lejay**: The preliminary study of a quartz tuning fork in a high vacuum. In the apparatus described, once the fork is started in oscillation, several hours elapse before the amplitude of the oscillations is reduced to one-half. The period was proved to be independent of the amplitude and constant within the limits of the accuracy of the measurements, about 0·0001 sec. Possible applications of the instrument are suggested.—**C. Raveau**: The rule of the four directions: Chatelier's principle.—**Henri Chaumat**: Electrostatic machines working with condensers.—**Gaston Rapin**: Attempts at the direct electrolytic preparation of ammonium permanganate. With an anode formed of silico-manganese in an ammoniacal solution, ammonium permanganate can be prepared directly, but on account of the low electrical conductivity of the ammonia solutions the method is of theoretical value only.—**S. Rosenblum**: The fine structure of the magnetic spectrum of the α-rays. The α-rays emitted by the radioactive substances radium-A, -C′ and thorium-C′ have been examined: the velocities of the α-rays attributed to these bodies are very homogeneous.—**F. Vlès and A. Ugo**: Some properties of the electromotive forces developed in contact with aqueous solutions of electrolytes of variable *p*H and salinity.—**Georges Fournier**: A magnitude permitting a new classification of atoms. Neither the atomic number N, nor the atomic weight A, completely defines an atom. The quantity $U = \frac{3}{4}A - N$ is suggested and is regarded as representing its filiation capacity.—**Guy Emschwiller**: The action of the zinc-copper couple on methylene iodide. In ether solution, ethylene is evolved and an organozinc compound formed. The latter appears to be zinc-iodomethyl iodide, ICH_2ZnI. With iodine, methylene iodide is regenerated; with water, methyl iodide, zinc hydroxide and zinc iodide are produced.—**Henri Moureu**: The tautomerism of the α-diketones. Heat of transformation of the isomers. The heat of transformation of the α-diketones (methylbenzylglyoxal, phenylbenzylglyoxal) is of the order of 2·5 large calories per molecule. This was determined in two ways, one based on the thermodynamic relation between the heat of transformation and the thermal variation of the equilibrium constant, the other on the heats of combustion.—**Jacques Bourcart and A. Keller**: The geological

sults of the Augiéras-Draper Sahara expedition retaceous and Eocene).—**Henri Erhart**: The nature d origin of the soils of Madagascar.—**Charles Rabot**: ne abnormal arrival of icebergs on the north coast Norway. For the first time on record, numerous ebergs (from Nova Zembla or Franz-Joseph Land) ve appeared on the north coast of Norway dur- g May last.—**R. Bureau**: Pressure and tempera- re by radiotelegraphy.—**Roger Heim**: The vasi- rm apparatus (*hyphes*) of the Agaricaceæ.—**Robert mesle**: The embryogeny of the Elatinaceæ. The velopment of the embryo in *Elatine Alsinastrum*. **J. Loiseleur**: The modifications of the collagen bstances under the action of the radiation from dioactive bodies. The β-radiation of radium or of don effects a profound alteration in the colloidal ate of collagen substances; salts of the heavy etals (lead acetate, gold chloride) sensitise the col- gen to the action of the radiation. The phenomenon independent of the temperature between 0° C. and ° C. and is proportional to the intensity of the diation.—**Lamberton**: The Archæoindris of Mada- scar.—**Robineau and Contremoulins**: Examples of ntheses and protheses in bone, in metal uncovered covered with rubber, established on metroradio- aphic data. Observations continued over several ars show that the tolerance of the organism is mplete if the mounting on the bone is correctly rried out.

CAPE TOWN.

Royal Society of South Africa, April 17.—**J. L. B. ith and R. H. Sapiro**: Some derivatives of thiazole. **G. E. Hutchinson, G. E. Pickford, and J. F. M. huurman**: Report on the natural history of pans and ner freshwaters of the Transvaal (see also NATURE, ne 1, p. 832).—**H. N. Dixon and H. A. Wager**: w and noteworthy mosses from South Africa.—**F. J. Schonland**: Thunderstorms and the penetrat- g rays. The main feature of the instrument used is electroscope in which the moving part is a very ht mica mirror suspended by two fine strips of gold f. Measurements of the intensity of the penetrat- g radiation underneath five active thunderstorms l not differ appreciably from measurements made ring periods of fine weather.—**W. A. Jolly**: On ording lymph-heart beats. The work was under- ken with the object of studying the action of the mph-hearts in Anura when the conditions are as arly as possible normal. The method employed is at of the optical lever. A minute fragment of vered cover-glass is placed on the skin—to which adheres—where the impulse is most distinct, and beam of light reflected from this mirror is focussed the slit of a photographic recorder furnished with oll of sensitised paper. The beat of the lymph- art recorded in this way is remarkably regular. e beat action is not continuous, but shows periods en it becomes very small or ceases altogether.

PRAGUE.

Czech (Bohemian) Academy of Arts and Sciences cond class, Natural Sciences and Medicine), ril 12.—**Fr. Ulrich**: Variscite and barrandite from nice, near Zbiroh.—**J. Švéda and R. Uzel**: De- mination of tin by rapid electro-analysis. After a ical examination of electro-analytical methods for the authors have worked out as the most reliable thin 0·32 per cent tin) the procedure in which tin leposited electrolytically from acid oxalate solu- is of stannous and stannic salts in the presence hydroxylamine.—**J. Bašta**: New aspects of the bility, resistance, and fragility of rails and wheels ailway engineering.

May 31.—**J. Wolf**: The organic cement substance of the bone and of the dentin.—**V. Tůma**: Histological changes in rats during avitaminosis.—**J. Janatka**: The development, structure, and significance of the nucleus pulposus of the intervertebral discs.—**J. Nešpor**: Differentiation and de-differentiation of the tissue cultures from the viewpoint of the vitality measurements.—**F. Chudáček**: Calcification of the costal cartilages.—**V. Janko**: The insular tissue of the adult pancreas of the Cyprinides, its form and its relation to the excretory system.—**M. Uher**: The development of the nervous elements *in vitro*.—**M. Mikan**: A certain Cremona correspondence in quadri-dimensional space.—**J. Sobotka**: A contribution to the solution of the generalised problem of Apollonius.—**J. Charvát and D. Gjurič**: The cause of Basedow's glycosury.

ROME.

Royal National Academy of the Lincei, April 21.—**V. Volterra**: Observations on hereditary phenomena.—**G. Loria**: The scientific manuscripts of Francesco Siacci.—**A. Tonolo**: Classification of the surfaces of Hilbertian space, the 2-tangent space of which is of four dimensions (1).—**L. Fantappiè**: Linear functional equations in the complex field.—**G. Mammana**: Certain applications of the theory of the decomposition of linear and homogeneous differential expressions to the study of homogeneous linear differential equations.—**Pia Nalli**: Derivation of a tensor along a line.—**A. Mambriani**: A theorem relative to ordinary differential equations of the second order.—**G. Scorza-Dragoni**: A particular differential equation.—**E. Pini**: The existence of integrals of ordinary differential equations.—**D. Pompeiu**: The unicity of the prolongation of harmonic functions.—**A. Palatini**: Einstein's new theory. By means of his new theory, and starting from a principle of Hamilton with an appropriate universal function, Einstein has arrived at satisfactory analytical results. These are, however, only a first approximation, and the methods adopted do not render it easy to follow the corresponding exact equations, which have not yet been obtained. In the present note it is shown how, by the systematic use of known operations, without further formal complications, such equations are readily derivable.—**L. Genovese**: Comparison of the photographic magnitudes of various zones of the Astrographic Catalogue.—**A. Belluigi**: Simple and rapid processes of topographic correction.—**C. Mineo**: Relations between the parameters of terrestrial ellipsoids and the values of gravity.—**I. Ranzi**: Phenomena of negative resistance in a diode subjected to a magnetic field.—**A. Occhialini**: The charge of emission centres as shown by the polarity of the electrodes. The results of experiments with magnesium, mercury, and lead show that, for each element, the ratios between the lengths of the lines for positive and negative polarity are equal for lines emitted from centres having the same charge, and different, and increasing with the order of ionisation, for lines emitted from centres ionised differently. These results may be utilised for distinguishing spark lines according to the order of ionisation of the emitting atom.—**S. Di Franco**: Natrolite from Viagrande (Etna). Crystals of natrolite found in the cavities of a very old, reddish lava show the specific gravity 2·19-2·21 and the axial ratios $a : b : c = 0{\cdot}978523 : 1 : 0{\cdot}353626$, which agree well with the measurements made by Brögger on Norwegian natrolite. No deviation in the direction of extinction is observable. Most of the water present in the mineral is expelled within a somewhat narrow range of temperature, namely, 290°-305°.—**M. Comel**: The

physiological action of strontium. Continued endomuscular administration of strontium hexose-oxypropionate to fowls causes a characteristic intoxication developed at the expense of the nervous system. The first symptom is wasting accompanied by a voracious appetite, nervous changes appearing later. The symptoms as a whole are reminiscent of those produced by lack of vitamin B and are to some extent attenuated by administration of this vitamin.—C. Guareschi: The otocysts of anuran amphibia considered as a mosaic system.—S. Pastore: A special method of staining malaria parasites.

The Advancement of Science in South Africa.

TWENTY-FOUR years ago the British Association visited South Africa for the first time, and now, by invitation of the South African Association for the Advancement of Science, the parent body is again in Cape Town. Mr. Jan H. Hofmeyr's inaugural address, which is printed in the supplement to this issue of NATURE, indicates the remarkable advances made since 1905 in South Africa in almost every branch of science. Mr. Hofmeyr very properly recognises the great service of the late Sir David Gill to science in South Africa in the early part of this century. Without him there would have been no body in South Africa corresponding to the British Association, for to him, and to a lesser extent Sir Charles Metcalfe, the existence of the South African Association is largely due. Sir David was not only a great astronomer, but also a very inspiring and attractive personality.

In 1905 there were four separate States, each enjoying, under the Crown, a very large measure of independence. Two of them, the Transvaal and the Orange Free State, as a result of the war, were still under Imperial tutelage, but in 1907 they were given full responsible government. It cannot be truthfully stated, however, that these four States formed a very happy family; indeed, the exact converse was the case, but in 1910 all came together and formed what is now known as the Union of South Africa. It was then that the real advances in scientific work started, for, thanks largely to a bulging Transvaal treasury, government departments were properly staffed with scientific workers. When it obtained responsible government in 1907 the Transvaal showed the way, possibly because it had the necessary money, and the world-renowned Veterinary Station at Onderstepoort to which Mr. Hofmeyr refers was actually planned before union took place.

Twenty-four years is not a long period, but possibly no other country has experienced such changes within a similar time. Governmental changes have already been indicated, but the whole country's physical aspect has altered almost beyond recognition. Vineyards, orchards, plantations, and trim homesteads now abound where formerly there was nothing but bare veldt. The flocks of sheep and cattle have increased beyond the wildest dreams of those who can recall the conditions of 1905. It is true that ostriches, thanks to fickle fashion, have decreased for the moment, as have also Angora

goats, but the nuclei of potentially important industries still remain. Great stretches of country which were deadly to man and beast are now being successfully farmed and healthy children are being reared. The fight against animal and plant diseases has been waged without ceasing and, thanks to the vigilance of an alert staff of scientific workers attached to the agricultural department, great victories have been won. In this connexion the work of Lord Milner must never be forgotten, for it was he, and no other, who laid the foundations of a scientific agricultural policy the results of which are so apparent to-day. This fight has been waged in the laboratories as well as in the veldt. Twenty-four years ago South Africa was importing many of its everyday food requirements, such as butter, cheese, and bacon. To-day she is exporting all these and many others, but she has still to import a considerable proportion of her wheat.

Sir Thomas Holland, the new president of the British Association, will find much to interest him in his own line of work, for in spite of the triumphs of agricultural science, South Africa is still in the minds of the public mainly a producer of gold, diamonds, and, to a minor extent, of platinum. The Geological Survey, from the merely material point of view, has brought much wealth to the country as a whole through its discoveries and surveys, and in Northern Rhodesia a most ambitious scheme of geophysical survey is now being undertaken. Two years ago, at the Empire Mining and Metallurgical Congress held in Canada, Sir Thomas delivered an epoch-making address in which he advocated the necessity of making a review of the mineral resources of the Empire, and though nothing tangible has resulted, his views have not been forgotten; and South Africa, which is probably as well known geologically and mineralogically as any other country in the world, is still capable of springing mineralogical surprises which increase her potential wealth. It is true that many, indeed most, of the discoveries have been made by the old-time prospector, but it looks as if the new geophysical methods were likely to oust that picturesque character from his most interesting occupation.

Then, although the Rand and Kimberley are still the most important mining centres, they have ceased to be the only ones. Indeed, it looks as if Northern Rhodesia will at no distant date rival the Rand with regard to the value of its output of copper and other metals and minerals. But throughout the Union itself there are many centres of mining activity concerned with the actual mining and subsequent treatment of coal, platinum, chrome, asbestos, mica, tin, manganese, magnesite, beryl, and other minerals of minor importance.

Not many years ago, the exports from South Africa were made up almost entirely of gold and diamonds, but to-day the agricultural products, as Mr. Hofmeyr points out, very nearly equal in value the mineral exports, and it is anticipated that at no distant date they will even exceed them. These great advances are undoubtedly due to the application of scientific principles, and although the amount of research work carried out in the laboratories of the four teaching universities of the country is comparatively small at the moment, that work is undoubtedly of paramount importance to South Africa itself.

Mr. Hofmeyr refers with justifiable pride to the great advances which have been made in university teaching—advances in which he himself took no mean part. There is, however, just a doubt as to whether they have not been too rapid for a country which, after all, has a white population of only a million and a half. Probably they were inevitable, as the distances between populous centres are very great, and there has always existed a healthy provincial patriotism which has made for duplication of services generally. There are, for example, two well-equipped medical schools when probably one is quite sufficient for the country's requirements. There is also overlapping in certain specific subjects. If, in the fullness of time, one of the existing universities could be developed for research and post-graduate teaching, the country would undoubtedly be the gainer. At present there is too much teaching and too little research, and yet, as has already been indicated, the output is quite considerable South Africa is fortunately very rich in historical archives, and thanks to Mr. Graham Botha, Sir George Cory, Prof. Eric Walker, and many other earnest workers, these are being rescued from comparative oblivion and made public.

Then, again, thanks to a few ardent workers inside and outside the universities, the origins of the native races, their languages, their folk-lore, and their customs, are being studied to-day as never before. The natives are being rapidly civilised, their old tribal customs are gradually dying out, and the authority of the chiefs, except in the native reserves, has practically disappeared. Nothing quite satisfactory has yet taken its place. The black man is South Africa's greatest problem to-day. All others fade into relative insignificance, and it will take the combined wisdom of both the

dominant races to reach a solution. The members of the British Association cannot be expected to grasp all the ethnological, economic, and political aspects of this great and most difficult problem in the short time at their disposal, but they can at least regard it from an entirely detached point of view.

Those who were living in South Africa at the time of the last meeting there of the British Association wondered very naturally what would be the effect of that very inspiring experience. They felt that they were on the eve of great happenings, but no one could predict what these would be.

Looking back, we find it difficult even to-day to assess the benefits which accrued to the country as a whole. Both visitors and hosts were undoubtedly inspired by the interchange of thought and experience, and it was surely no coincidence that, immediately after the visit, South Africa as a whole set out to wage scientific warfare on its all too numerous pests and parasites, to discover the possibilities of new forms of agriculture, and to inaugurate a more extensive geological survey campaign. The people as a whole, and those who were responsible for the government of the country, had their thoughts very definitely directed to the application of scientific endeavour.

Those who live in South Africa, and those outside it who endeavour through sheer love of that great country to keep in touch with its many problems, again feel that they are on the eve of great happenings. What they will be no one can say, but the members of the British Association will find a better educated community, a more receptive public, and a greater appreciation of the benefits of science among all classes than on the last occasion. They will also find a very healthy spirit of nationalism, developed largely since the War, but finding expression in all walks of life. Nevertheless, they are assured in advance of a hearty welcome from all sections of the community, and we have no doubt that not only will the present visit be as inspiring as the last, but also that its results will be infinitely more beneficial, not to South Africa alone, but to the whole of the British Empire and to the world at large.

The British Association when it visits an outpost of the Empire acts as a catalyst; little is known about the methods whereby these mysterious bodies exercise their equally mysterious effects, but they are nevertheless perfectly definite. South Africa is a splendid field for this catalyst, and we are sure that the stimulus afforded by the present meeting will be felt for many years.

A Classic of Physics.

The Collected Works of J. Willard Gibbs. In 2 vols. Vol. 1: *Thermodynamics.* Pp. xxviii + 434. 15*s.* net. Vol. 2: Part i., *Elementary Principles in Statistical Mechanics*; Part ii., *Dynamics, Vector Analysis, and Multiple Algebra, Electromagnetic Theory of Light, etc.* Pp. xviii + 207 + vi + 284. 15*s.* net. (New York, London and Toronto: Longmans, Green and Co., Ltd., 1928.) 2 vols., 25*s.* net.

THE writings of Gibbs on thermodynamics and statistical theory were far and away the most complete of the early presentations of those subjects, but there must be many with a good knowledge of the theories who have never consulted the originals. As his works have long been out-of-print, the editors have performed a most valuable service in bringing out the present two volumes. They are beautifully printed, and the editors are to be congratulated on having adopted the right method for the re-issue of a classic; a commentary will certainly be useful, and one is to be composed by a number of authorities, but the present books are not disfigured by footnotes in the manner so often practised by energetic but injudicious editors.

It is well known that Gibbs's work did not meet with great appreciation for many years, and after reading his papers it is interesting to consider why. We can imagine some elder of the Connecticut Academy after one of their meetings telling him as delicately as possible that he could not understand what the "Heterogeneous Equilibria" was about; and then Gibbs would go home and amplify it, expecting thereby to make it as clear to others as to himself. The result is that, once the chief idea is grasped, the whole is discussed in such great detail that it could scarcely be improved in ease or clearness. The whole trouble is at the beginning, and depends on the reader being able to *feel* the meaning of $d\epsilon \geqslant td\eta - pdv - \mu_1 dm_1 - \mu_2 dm_2 - \ldots$ (Gibbs always considers the case of inequality with care), and for most of us it is unfortunately a considerable step from admitting the logic of the equation to the intuitive understanding of it. It is hard to see how amplifying his introduction would have helped; what is needed is habit of thought, and this can only grow with the lapse of time. His first paper on thermodynamics was published in 1873, two years before the great paper, and the right answer to anyone who complains about the "Heterogeneous Equilibria" is to advise him to spend, like Gibbs, two years over its preliminaries.

LAWRENCE Public Library

The same qualities appear in the "Statistical Mechanics". There is the same novelty in the initial idea of a *canonical ensemble*, and the same admirably lucid and detailed account of its consequences, leading gently towards the principles of thermodynamics—with at the end a clear perception of the difficulties of radiation. It is always interesting to ask any physicist whether he prefers Gibbs's foundation of statistics or that based on the ideas of Maxwell and Boltzmann. Everyone agrees that an assumption must be made somewhere, but different qualities of mind like to take it differently. Some prefer to follow Gibbs in the conception of the *canonical ensemble*, a very explicit assumption, but one which is not obvious enough to be classed as axiomatic—especially as he uses it in Chap. xv., where the rather abstruse conception of the thermodynamic potential seems to spring complete out of nothing. Others prefer to go behind the *canonical ensemble* by using the *microcanonical*, in which the systems considered all have the same energy and number of atoms. There is no doubt that this idea is more easily grasped and is more plausible, but closer examination shows that it merely conceals the same fundamental difficulties rather more deeply. Gibbs discusses it in one chapter, but his treatment is only really to show that it approximates to the *canonical*. With modern technical methods the *microcanonical ensemble* is as easily discussed as the other, and presents us with the temperature and potentials as obvious mathematical consequences of the calculus; it is tempting to believe that if Gibbs had known of this calculus he would have put the *microcanonical ensemble* in a more prominent position.

These two great works show Gibbs's main character, a capacity for quietly puzzling out a whole field of thought entirely by himself, and getting it into perfect order. That was his main quality, but it was made possible for him by a second quality, and one rather unexpected in a man whose whole work was devoted to natural philosophy. This is a capacity for deep symbolism, and in reading his work we have the feeling that he got more enjoyment out of this mathematical quality than from its physical applications. This is exemplified in the "Heterogeneous Equilibria" by the masterly way in which he handles the variational symbols d, δ, and D (but never ∂). The same mathematical taste comes out even more strongly in his papers on vector analysis, which are the only ones in which any trace of personal feeling appears.

It is one of the perversities of humanity, that we get more excited about notations than about the things they represent. Gibbs's vector notation was attacked by Tait, who championed Hamilton's quaternions with a very undue asperity, and Gibbs's reply, though much more restrained, was largely a counter-attack on Hamilton. The symbolism of vectors has gone through many changes, and even now we can scarcely pronounce a final judgment. The quaternion certainly has a much more limited scope, for though it is better than other methods to deal with rotations, it cannot represent tensors; and it has a brutal directness which must have been repugnant to the symbolic mind of Gibbs. His method, on the other hand, started from the very broad ideas of multiple algebra, and was based on the 'dyadic', essentially a tensor. A few years ago it would have been said that neither of them was the right notation, certainly not the quaternion, and scarcely the dyadic; for, if we want to go beyond the mere idea of vectors, we had better be able to describe tensors of any rank, which can be done admirably by the use of subscript letters. But, curiously enough, in the last year both Gibbs and Hamilton have been reinstated, Gibbs because his notation is that of matrices, which play such a part in the quantum theory, and Hamilton, because the quantities used in expressing the 'spinning electron' have a peculiar quaternion-like flavour and are quite unlike ordinary vectors.

After reading through all Gibbs's works one is naturally drawn to make an estimate of what were the peculiar qualities of the man. A rough dichotomy of great men of science can be made into those who achieve their greatness by understanding things, and those who achieve it because they know what they do not understand. The first type, of which Kelvin was an example, seems to have been born with a direct comprehension of some part of Nature and only has to grow up in order to explain it. The second type works in quite a different way, by puzzling out the things it does not understand. Rayleigh was of this type, and so was Gibbs, and it is interesting to remember that Kelvin did not think much of Gibbs's work. But though we have likened him to Rayleigh, there was a very great difference between them; for Rayleigh wanted to understand anything that turned up, whether it was the general theory of radiation or how much grease there is on clean water, whereas Gibbs was only interested in principles, and undertook the more practical of his works merely in order to convince others that his principles were useful. It is this steadfast study of broad principles that constitutes his greatness.

The Hellenic Society, 1879–1929.

he Journal of Hellenic Studies. Vol. 49. Part 1. Pp. 139 + xcvii + 6 plates. (London: Macmillan and Co., Ltd., 1929.) 21*s.* net.

THE celebration of the fiftieth anniversary of the Society for the Promotion of Hellenic tudies in June last has been made the occasion r the publication of a history of the Society, hich appears as a supplement to the recent sue of the Society's journal. The task of telling ie story could have been entrusted to no more ompetent author than Mr. George Macmillan. He one of the few remaining original members, he cted as honorary secretary from the inception of ie Society until 1919, and is now its honorary easurer; but beyond this the idea of the forma- on of such a society was his, and it was due to m and to Prof. Sayce, with the staunch support Mr. (afterwards Sir) Charles Newton, that the ociety came into being in 1879. Mr. Macmillan had so profited much by the support and advice of M. ennadius, then Minister for Greece in Great Britain. It is perhaps not easy in these days, when cieties seem to spring up with comparatively tle effort, to realise the courage required in the eventies to carry through such an undertaking as ie formation of a society for the study of such a bject as ancient and modern Greek language and lture. Further, the invitation to join the Society as originally issued only to those who had been Greece—not in those days a very large number. hen once it was constituted, however, the com- ittee was to have the power "to elect such other rsons as are interested in its objects". The sponse to the personal appeal issued by Mr. acmillan and Prof. Sayce was immediate and thusiastic, and almost at once the numbers grew beyond their hopes. The early lists of supporters mprise the flower of British classical scholarship; ut the immediate success of the Society and the ise administration of its affairs, which have placed in the front rank of the learned societies of Great ritain, were due to the energy and never-failing thusiasm of Mr. Macmillan, ably seconded by r Charles Newton.

Mr. Macmillan's history of the Society falls into o parts. The first part covers up to the year 04 and was originally written for the twenty- th anniversary. Although this is only reissued order to make the survey of the whole period mplete, it may not be out of place to recall some the activities for which the Society was directly sponsible or with which it has been associated, as a reminder of the debt owed by scholarship to those who have been responsible for its policy and administration. Foremost among such activities is the *Journal of Hellenic Studies*, of which the first volume appeared in 1880. Some anxiety was expressed at the time lest the venture might fail to maintain its vigour after the first interest had died away. These fears were ill-founded. The *Journal* has had among its contributors such men as Schliemann, Colvin, Imhoof Blumer, Sir W. M. Ramsay, Sir Arthur Evans, and D. G. Hogarth, to name only a few—men whose reputations are imperishable while the life and literature of ancient Greece are of account in intellectual culture. Many of the contributions to its pages will be of supreme authority, each in its special branch of study, for generations, and the frequency of the references to the *Journal* in standard works, in classical studies, and in archæology bears witness to its repute.

Among the original purposes of the Society was the publication of copies and photographs of Greek monuments and inscriptions of all kinds. It was also intended to assist travellers and students by providing or arranging for the provision of certain facilities and conveniences in Greece itself. Herein lay the germs of the most useful and fruitful of the activities undertaken by the Society. On one side it came to take an active part in promoting the exploration of the ancient sites of Greece and Asia Minor; on the other, it brought the full weight of its influence to bear on the movement, initiated by Sir Richard Jebb, for the foundation of the British School of Archæology in Athens, and, at a later stage, to assist in founding the sister School of Archæology in Rome. Even before the foundation of the School in Athens in 1886, the Council in 1881 had helped to finance W. M. Ramsay in an archæological expedition to Asia Minor by voting £150 for the expenses of a draughtsman. The results of this expedition encouraged the Council to further efforts, and an Asia Minor Exploration Fund was instituted to carry on the work. This was the first only of a number of funds for similar purposes. Grants were made for work at Naukratis, Thasos, in Caria and on the site of Alexandria. A Cyprus Exploration Fund, established in 1886, was followed by a Cretan Exploration Fund in 1899 under the direction of Sir Arthur Evans, Dr. D. G. Hogarth, and Mr. R. C. Bosanquet. The important results to follow on this last undertaking need no emphasis; but they stimulated the British School to undertake a Cretan excavation of its own at Palaekastro in 1902.

The history of the Society between 1904 and the present year is a record of steady work and expansion stimulated by the discoveries of Sir Arthur Evans in Crete and of the members of the British School both in Crete and on the mainland. The work was sadly interrupted by the War and the Society paid its toll from among its younger members. The special knowledge of the Near East possessed by members of the Society and of the British School was an asset in the Eastern theatres of war, of which full advantage was taken and the nature of which is perhaps only imperfectly realised.

In 1908 the library had grown beyond the capacity of its original quarters in the premises of the Royal Asiatic Society at 22 Albemarle Street, and in the following year it moved to 19 Bloomsbury Square. In 1910–11 the premises were extended to accommodate the offices of the British Schools at Athens and Rome, and, by a wise decision, a common library and collection of photographs and lantern slides for the three bodies was formed. It was not long, however, before this arrangement led to the necessity for still further increase in accommodation, and latterly a house has been acquired in Bedford Square, as is recorded in the Report for 1925–26, where the Society is likely to remain for at least another generation.

In these days, when interest in classical scholarship in the narrower and more restricted sense is thought to be on the wane, the prosperity and growth of the Society for the Promotion of Hellenic Studies may be taken as a gratifying sign that the culture of the Mediterranean, so important in the history of civilisation, still holds its own in the interests of an influential section of the community. We wish the Society an increasingly prosperous and productive future.

The Subject Index to Periodicals.

The Subject Index to Periodicals, 1927. Issued by the Library Association. Pp. x + 299. (London: The Library Association, 1929.) 70*s.* net.

THIS Index was commenced in 1915 as a successor to Poole's Index, which had ceased some years earlier. The present volume sets out to arrange alphabetically by subjects the more important articles in some 600 periodicals, mainly in the English language and of a general character, covering the principal English scientific and technical periodicals, but excluding most of the specialist and semi-technical periodicals and foreign scientific and technical journals. The Index caters only for such inquiries as may be expected to confront a general librarian. From this point of view it is very well done, the get-up is excellent in every way, and, considering the labour of compilation, which is only to be comprehended by those who have undertaken similar work, the price is not high.

The only serious blemish one can find in the work is the system of alphabetical subject headings, devoid of even a rudimentary classification, in which confusion appears in the garb of simplicity. It is doubtful, in view of the intricate network of cross-references required, whether there is any less labour involved in compiling the Index on this principle rather than on a classified system; whilst the labour thrown on to the searcher, who must progress painfully through the tortuous labyrinth of cross-references, is augmented disproportionately. The preface states that the alphabetical headings of the Library of Congress have been used in the main. It would have been advantageous to employ the Library of Congress Classification itself, or, better, a classification which is comprehensive enough to permit periodical literature to be classified—such as the Universal Decimal Classification.

The faults in the Index, which even the most cursory examination reveals, are those that are inseparable from the system adopted, and which no reasonable amount of care on the part of the collaborators could have avoided, namely, the juxtaposition of incongruous subjects, and the separation of related ones. The entry, under the heading "Cells", together with articles on living cells, of a paper on the geometrical properties of space—stackability of tetrakaidecahedra—is reminiscent of the bibliographer's classification of "Lead, kindly light" with "Lead pipes". If one would study the properties of living cells, one finds two papers under "Cells", with cross-references to "Embryology", "Golgi Apparatus", "Karyokinesis", "Plant Cells" and "Tumers", and under each of these headings there are several further cross-references, and so on. Would one investigate the acoustics of buildings; from "Acoustics" there is a reference to "Sound", and vice versa. "Acoustics" leads to "Architectural Acoustics", where one finds eight papers, and to "Music: Acoustics", with no papers. From "Sound" one reaches "Music: Acoustics" again, thence coming back to "Architectural Acoustics", but with a reference also to "Echo", where two more papers are found, though no reference to the Albert Hall echo occurs here. This must be found under "Albert Hall". But a reference to that heading is given under "Architectural Acoustics". This heading also leads to "Buildings: Sound-proofing", with three

papers, and "Church Architecture", with two. Looking for articles on geophysical prospecting, one finds none under "Geophysics", but there is a cross-reference to "Prospecting" where there is one article. This leads to "Electrical Prospecting", with one more, and thence to "Torsion Balance" with another article. There is no reference to a paper on "Applications of sound-prospecting to geophysics", which is listed under "Sound: Propagation". If the subject were more comprehensive, the maze of cross-references would be still more bewildering, leading in the end to the collection of references to the papers of only a single year.

In spite of the system, however, the work should be recommended as a very useful index for the general librarian and for the reader who does not need to exhaust his subject.

S. C. BRADFORD.

Our Bookshelf.

Field and Colliery Surveying: a Text-book for Students of Mining and Civil Engineering Surveying. By T. A. O'Donahue and T. G. Bocking. New and revised edition. Pp. xvi + 327. (London: Macmillan and Co., Ltd., 1928.) 10*s.* 6*d.* net.

THIS book has been reprinted, sometimes with additions and revisions, no less than thirteen times. Past success guarantees the success of an able revision. The size of page of the present edition has increased by some fifteen per cent, and there are fourteen more pages, while much of the groundwork in geometry and mensuration has been wisely omitted to make room for descriptions of improvements in surveying instruments and methods. The original author has been joined by Mr. T. G. Bocking, a surveyor well known not only in practice but also by his important contributions to the periodical press and to the *Transactions* of the Institution of Mining Engineers. Both authors are prominent in the mining profession: both have had experience as examiners; the collaboration is therefore a happy one and is also to be welcomed because, while one author obtained his early experience in the north, the other has had experience both as a civil and mining engineer mainly in the midlands and the south. This revision has purged the book of some localisms of practice and provincialisms of expression.

The book should now be fairly representative of the survey practice in many British coalfields. But it is clearly not a complete exposition, and the only excuse for its sub-title is that it will be useful to pupils of firms styling themselves "Civil and Mining Engineers". The preference of Mr. Bocking for his three-tripod theodolitic outfit is made clear, but this scarcely warrants the extreme brevity of the treatment of the Galletly modification; and his curt dismissal of one-tripod outfits in a few lines is regrettable. His generalisation that "a surveyor should learn to dispense with this additional complication (a centring device) and become experienced in setting up expeditiously and accurately without it" is only valid for three-tripod outfits; applied to one-tripod outfits, it is a case of Bocking *contra mundum*. For such devices abound; every firm of instrument-makers of whatever nationality manufactures them; and they are universally adopted underground and generally for surfacial surveys.

The selected instance of a traverse of 8505 ft. with closing errors of $e_x = -1{\cdot}79$ ft., $e_y = -0{\cdot}96$ ft., $e_z = \pm 0{\cdot}26$ ft. does not prove the excellence of Mr. Bocking's outfit and method, for accidental errors are most commonly mutually destructive, and the most probable aggregate of such errors is zero; what it does show is lack of sympathy with the modern practice of teaching university students to test the performances of instruments from statistics by averaging, or by the method of least squares, and thus more rapidly and surely to arrive at conclusions which the surveyor anciently formed from the impressions of a lifelong experience!

L. H. COOKE.

Probleme der kosmischen Physik. Herausgegeben von Prof. Christian Jensen und Prof. Dr. Arnold Schwassmann. Band 11: *Das Zodiakallicht; sein Wesen, seine kosmische oder tellurische Stellung.* Von Dr. Friedrich Schmid. Pp. x + 132 + 4 Tafeln. (Hamburg: Henri Grand, 1928.) 10·50 gold marks.

THIS excellent series of monographs serves a valuable purpose in providing separate works on many interesting natural phenomena, and not least in the case of those of minor interest, the literature of which is fragmentary and widely scattered; workers in other fields can turn to these books with fair confidence that they will find all the important facts and theories concerning the respective subjects. In particular this is the case with the volume under review, which appears to be almost the first book expressly devoted to the zodiacal light; the author is an enthusiastic student of the subject, and has observed it systematically for nearly forty years. The volume is of great interest both on the side of observation and on that of theory; it may be hoped that it will lead others to observe the zodiacal light regularly, especially since the way in which the position and form of the light vary with the latitude and longitude of the station of observation is not yet adequately known.

The main theoretical question involved in the subject is whether the rarefied matter which, by reflection of sunlight, produces the zodiacal light, is distributed throughout the solar system up to or beyond the earth's orbit, or whether it is merely a terrestrial appendage. The author argues cogently for the latter view; he regards the zodiacal light as the highest and last twilight bow produced by the bending of light in the earth's atmosphere. The theory implies an immense extension of the earth's atmosphere, with an oblateness in a plane

coinciding more nearly with the ecliptic than with the equator, and therefore not explicable merely by the rotation of the outer atmosphere with the rest of the earth.

In the discussion of this part of his subject the author's speculations range rather widely, but the atmosphere presents us with so many inescapable riddles that the addition of one more, relating to its most inaccessible regions, is only in keeping with its character. The terrestrial origin of the zodiacal light is rendered more probable by the existence of a zodiacal light associated with the moon.

The Problem of Motor Transport: an Economic Analysis. By Christopher T. Brunner. Pp. 187. (London: Ernest Benn, Ltd., 1928.) 12*s.* 6*d.* net.

EVERY return of motor traffic in every country shows an ever-increasing number of cars and lorries in use, and though it was only in 1907, as we are reminded by Mr. Brunner, that Mr. Asquith referred to motor-cars as "a luxury which is apt to degenerate into a nuisance", the petrol-driven vehicle is bringing about a change in our modes of travel comparable only to the revolution effected by the railway. Mass production places the motor-car at the service of the man of modest means, and if he cannot afford a car himself, he is a customer of the bus and charabanc owner.

Motor transport problems are therefore always with us, and to those who want a general review of them a better book than Mr. Brunner's would be hard to find. It does not tell the reader how to choose or run a car, but it tells him something about the questions of taxation, traffic, rail and road competition, the economics of special motor roads, why railway companies retain horses, and how roads are maintained. Incidentally, on p. 120 the author tells us that the idea of tarring roads originated with a workman of Hythe, who tarred the road in front of his own house at his own expense. Hythe boasts of being the birthplace of one great pioneer, Sir Francis Pettit Smith—'Screw' Smith—the chief promotor of screw propulsion, and there is a tablet in the High Street to his memory. If Mr. Brunner is correct, Hythe should certainly tell us the name of this workman who has been a benefactor to millions of motorists, and to still more millions of pedestrians.

Das Prinzip der kleinsten Wirkung von Leibniz bis zur Gegenwart. Von Adolf Kneser. (Wissenschaftliche Grundfragen: Philosophische Abhandlungen, herausgegeben von R. Hönigswald, Band 9.) Pp. ii+70. (Leipzig und Berlin: B. G. Teubner, 1928.) 4 gold marks.

THIS pamphlet deals with the principle of least action, chiefly from a philosophical and historical point of view. A few pages are given to the mathematical aspect, which the author, who has written on the calculus of variations, is exceptionally well qualified to discuss. It is often asserted that the principle was due to Maupertuis, but it is here shown that the idea was enunciated much earlier by Leibniz. His arguments were of a theological nature, and might not appeal to present-day scientific workers, but it is remarkable how much of the work of Einstein and others is in the form that Leibniz asserted could be given to every physical law.

Strangely enough, Prof. Kneser, while discussing the use of the principle of least action in the theory of relativity, says nothing of the important part that it has played in establishing the new science of wave mechanics. It was the analogy between the principle of least action and Fermat's principle of least time that suggested an analogy between mechanics and optics, and led de Broglie and Schrödinger to such important results.

The Tragedy of the Italia: *With the Rescuers to the Red Tent.* By Davide Giudici. Pp. viii+216+34 plates. (London: Ernest Benn, Ltd., 1928.) 12*s.* 6*d.* net.

THE author of this book is an Italian newspaper correspondent who was the only journalist on board the *Krassin*, the Russian ice-breaker that took a prominent part in the rescue of the crew of the *Italia* airship off Spitsbergen in the spring of last year. His story is supplemented by accounts of several of the survivors. The *Italia* was wrecked off North East Land on a return flight from the North Pole. The cause of the disaster is not clear, but the result of it was the loss of seventeen lives, including that of Capt. R. Amundsen, who gallantly flew to the rescue, and the expenditure of large sums of money on search expeditions. In these operations the *Krassin* took a notable part. The ship was well handled, but her consumption of fuel, as much as 150 tons a day in open water, limited her sphere of work, and she was unable to force a passage in ice more than about six feet in thickness. In her second voyage, in September, the *Krassin* crossed the unexplored seas north of Giels Land on the way to Franz Josef Land. No new land was found.

Typical Flies: a Photographic Atlas of Diptera. By E. K. Pearce. Series 3. Pp. xv+64. (Cambridge: At the University Press, 1928.) 10*s.* net.

THIS atlas is intended to help the beginner and attract attention to an order of insects the study of which is hampered by the lack of elementary treatises. Like its predecessors, it is essentially a picture book and its object is to illustrate typical British flies by means of annotated half-tone figures. The venation and general appearance of many Diptera are well portrayed by this method, and comparisons with the illustrations should enable the beginner to sort out a considerable proportion of his specimens into their major groups. In the case of the more striking examples, generic or, here and there, specific identifications are also possible. The atlas is uniform with its predecessors, and the standard of execution of the attractive plates is well maintained.

Diffraction of X-rays by Two-Dimensional Crystal Lattice.

UNDER this title, W. Linnik, of the Leningrad Optical Institute, described in a recent issue of NATURE (April 20) an effect obtained with copper $K\alpha$ radiation and a mica crystal. A narrow beam of X-rays was passed through a cleavage plate of mica, which had previously been heated to redness and cooled. A photograph of the diffracted beam showed a series of spots, the arrangement of which is attributed by Linnik to the action of very thin layers of the crystal as independent *two-dimensional* gratings. It is supposed that "the space effect will be destroyed by the incoherence of waves produced by scattering from incorrectly spaced layers", the heat treatment having broken up the mica into very thin plates without disturbing their orientation. The arrangement of the diffracted beams corresponds to the pseudo-hexagonal network of points at intervals of 5·2 A. in the cleavage plane (001), which is so striking a feature of the mica structure.

I do not think it is necessary to postulate diffraction by a two-dimensional lattice in order to explain Linnik's results; they can be ascribed on the other hand to diffraction of the familiar type by the three-dimensional crystal grating, provided that one may assume the mica to consist of a number of flakes not quite parallel to each other. The normals to these flakes have a random orientation about a certain mean position, though the flakes themselves retain their relative position in the sense that there is no rotation of one flake over another around the mean normal.

To test whether such a structure of the mica plate would produce the effect observed by Linnik, the following experiment was tried by Mr. W. H. Taylor and myself. A cleaved section of muscovite mica, 0·6 mm. in thickness, was set up approximately normal to a narrow beam of molybdenum K radiation. During the exposure of a photographic plate, the section was rotated over a small range around both horizontal and vertical axes normal to the X-ray beam. The effect of this double rotation is to make the normal assume in turn all positions within a small solid angle extending five degrees in every direction from its mean position. The resulting photograph (Fig. 1), while showing more spots owing to the shorter wave-length, has precisely the same appearance as that published by Linnik. There is a complete and fairly uniform series of spots such as would be made by a two-dimensional grating, though in this case the crystal was quite normal and there is no reason to ascribe the effects to anything but the familiar three-dimensional diffraction. When kept stationary the crystal gave a Laue pattern; when heated this was partly replaced by the pattern of Fig. 1, though we did not succeed in obtaining so symmetrical a pattern with the heated crystal as that obtained by Linnik.

This simulation of a two-dimensional grating effect can be readily understood if the mechanism of diffraction is considered. Two of the three conditions for the diffraction of a monochromatic beam are imposed by the spacing of the points on the basal net (the cleavage plane (001)). Thus any diffracted beams which appear must have such positions as are to be expected from this two-dimensional grating. It can readily be calculated that the slight rocking to and fro of the mica does not appreciably affect these positions, a result familiar in the optical grating when the angle of diffraction is small. The third condition for diffraction is achieved by the oscillation of the crystal. Owing to the great length of the c axis (20 A.) a very slight rocking of the crystal (or warping of its surface) will suffice to bring points in successive c planes into such a relative position that reinforcement takes place.

To put this more precisely, when a point on the plate is formed by reflection from the plane (hkl), its

FIG. 1.

position only depends on h and k, being independent of l if second-order corrections are neglected. A rocking of $6\frac{1}{2}°$ in every direction ensures that, for every value of h and k, some plane hkl comes into position for reflection. If h and k are large, many values of l are possible, and the corresponding spot is due to the superposition of several diffracted beams.

It is interesting to follow the changes to be expected as the wave-length is shortened. The spots will crowd towards the centre and form a more and more regular triangular pattern. Each outer spot is formed by the co-operation of a number of planes differing in index l; hence an average between weakly and strongly reflecting planes is struck and the outer spots will be regular in intensity. The photograph will in fact repeat all the features shown in the results of Kikuchi (*Japanese Journal of Physics*, **5**, 2; 1928) on the diffraction of electrons by mica, quoted by Linnik. Its appearance can be readily explained by the familiar laws of diffraction by a three-dimensional grating, assuming a slight random warping of the mica planes. It is not necessary either in the case of electron diffraction or X-ray diffraction to assume that the crystal acts as a two-dimensional grating.

Asymmetry in the Radiation from the Hydrogen Atom in the Electric Field.

IN my monograph "Axialität der Lichtemission und Atomstruktur" (Polytechnische Buchhandlung A. Seydel, Berlin, 1927) I have discussed a case of asymmetry of radiation; if atoms of an element, say of helium, pass through a gas such as hydrogen, under certain conditions for some spectral lines of the moving atoms the radiation in the direction opposite

to the movement is more intense than in the direction of the moving atoms. This phenomenon is one of the facts on which I have based the conclusion that the atoms of the chemical elements have an axial structure and that the emission of light from a single atom is of vortical structure (*Lichtwirbel*) (cf. my monograph "Atomstruktur und Atombindung", Polytechnische Buchhandlung A. Seydel, Berlin, 1928).

Guided by this idea of axiality of atomic structure and emission of light, I have recently discovered an asymmetry in the radiation emitted by atoms in an electric field. Certain lines of the radiation emitted along the axis of a superimposed electric field have different intensities in the two directions of this axis or, more generally, different intensities for the two sides of the plane perpendicular to this axis.

The most important of my observations were made on the hydrogen lines Hα, Hβ, Hγ, and Hδ for the case of the emission along the axis of the superimposed electrical field, and show the following general phenomena.

There are emitted along the axis of the electric field those components of the hydrogen lines which appear electrically normally vibrating to the axis of the field when the axis of vision is normal to the axis of the field. This holds for the components displaced towards the red ('red') and also for the components displaced towards the violet ('violet'); however, the violet components are emitted more intensely in the direction of the field than in the opposite direction, while, on the contrary, the red components are emitted more intensely in the direction opposite to the field than in the direction of the field. This phenomenon explains an observation made independently by Mr. Wierl, that for the line Hγ in the case in which the axis of vision is opposite to the direction of the field, the violet components appear more intense than the red components.

This asymmetry of radiation of the hydrogen atom in the electric field is incompatible with the Bohr-Epstein-Kramers theory and with the Heisenberg-Schrödinger theory of the intensity of radiation of the hydrogen atom in the electric field, as also with the Sommerfeld theorem, founded on this theory, on the symmetry of the hydrogen atom; for these theories require that the intensity of the radiation should be symmetrical to the plane normal to the axis of the electric field. J. STARK.

Grosshesselohe-München, June 28.

The 'Absolute' and 'Relative'.

IT might serve a useful scientific purpose to point out some remarkable anomalies that have resulted from attempts to deduce philosophical conclusions from the findings of pure scientific research. Modern science has as yet no philosophy of its own, but the significance of its great achievements *experimentally* cannot be interpreted legitimately by means of the *speculative* philosophy of the school-men. Much attention has been paid to the general reader by writers who try to explain physical phenomena 'philosophically' without a clearly defined technical vocabulary. That such attempts have been premature and ill-considered is evident by the confusion in the minds of many persons, lay and scientific, as to the future of science.

For example: some statements in NATURE (June 22, p. 954) concerning "Psychological Conceptions in Other Sciences" are so alarming as to cause one to inquire whether it be the intention of workers in pure research to cease work and shut up their laboratories. Even though the conditions that determine quantum 'jumps' cannot be detected by instruments at present in use, are *we* entitled to jump to the conclusion that "structure and entities [now under observation are] in themselves unknowable and unimaginable"? Have we, indeed, reached the limit of possible human knowledge? The remark above cited is prefaced by the statement of Dr. Myers that "with the development of knowledge, ideas of the 'absolute' have been gradually replaced by those of the 'relative'". Further *development* of knowledge seems doubtful if individual entities are in fact unknowable! However, conceptions of 'relativity' appear to dominate the field, at present, to such an extent that one almost questions the sincerity of the search for a unitary field theory to synthesise relative conditions. Is it a really serious quest or merely a competition *pour passer le temps*?

While illogical, this attitude is consistent with the spirit of an age that would repudiate the principle of cause and effect physically as morally. Still, the innate tendency of the human mind to seek for a 'cause' cannot be wholly repressed. Some types of mind feel compelled to account for the behaviour of the blind forces of Nature, regardless of the temporary experimental *impasse*; and they have arbitrarily attributed to these forces a power of choice and self-direction supposed to be exercised by human beings. There is no scientific 'cause' behind the electron! Physical phenomena occur as and when a 'decision' is made by a capricious entity or electron which, like a god of popular mythology, has the power, apparently, to act as it 'chooses' or 'prefers', whatever the environmental conditions. Surely this is suspiciously like absolutism in the sense understood by democratic entities?

To speak, however, of having 'ideas about the absolute' is one of the many contemporary illustrations of a contradiction in terms. To conceive it possible to form *any* idea to represent the absolute is the cardinal error of theological and idealist philosophies the absolute deity of which is a decidedly relative individual discarded by science some generations ago.

In the article (NATURE, June 1 and 8), "Einstein's and other Unitary Field Theories: An Explanation for the General Reader", Prof. Piaggio refers to Newton's belief in absolute rotation. As the great Newton cannot have been an illogical thinker, it should be worth while to examine the basis of this belief. We who function in finite, relative matter are unable, obviously, to contact, record, or describe an infinite, absolute energy, if such there be. But, though we cannot imagine a state of rotation *per se*, physics, to be logical, must postulate a perpetual, self-generating motion as the uncreated, causeless cause of known and knowable material velocities. *In-finite* (without end or beginning), *when ascribed to energy, means ceaseless*, that is *without intervals*—a state that cannot be conceived mentally but, nevertheless, a logical and necessary hypothesis. For, if there be no such absolute perpetuity or infinity, how do relative conditions come into existence and how are they maintained in their interrelated activities?

While research is inducing a greater respect for the scientific knowledge of former ages, no investigation has been made by science into the philosophical rationale of the ancient arts of alchemy, astronomy, medicine, psychology, etc. Consequently, we attribute ideas of popular religions to the ancient scientific philosophers whose only deity was absolute motion. "Everything is full of gods," Thales said, because 'gods' and 'atoms' were synonymous terms. It is possible that there may be renewed appreciation of Newton's science when his philosophy is understood.

June 23.

New Fixatives for Plant Cytology.

FOR the study of somatic chromosomes a fixative is required that penetrates quickly, but does not shrink the cytoplasm; that spreads the chromosomes for counting, and gives clear definition of constrictions and trabants. Carnoy spreads the chromosomes out well, but most of the definition is lost. Flemming and its modifications are most useful, giving very good results, but there are some plants for which they are not suitable. Some plants, however, cannot be fixed well by any of our present methods.

In the course of work with *Primula sinensis* a number of fixatives were tried, among others the following new formula, which was found to give excellent results:

1 per cent Chromic acid	90 c.c.
Potassium bichromate	1 gm.
Sodium sulphate	0·5 gm.
Urea	1 gm.
5 per cent Glacial acetic acid	10 c.c.
2 per cent Osmic acid	15 c.c.
Distilled water	45 c.c.

The method employed is similar to that used with Flemming solution. Material is immersed in the solution for several minutes under an air pump to remove air and to aid penetration, and then it remains in the solution for a further twelve hours. After embedding in paraffin, cutting and mounting in the usual way, the slides are bleached in 1 part hydrogen peroxide in 10 parts 70 per cent alcohol for two to three hours. They are then placed in an iodine solution for a minute or two to remove any remaining bichromate. Material can be stained with gentian violet (Newton's method), hæmatoxylin, or other cytological stains in common use.

Excellent results have been obtained with *Papaver*, *Melandrium*, *Datura*, and *Pentstemon lævigatus* (with 96 chromosomes), and a comparative test of several fixatives, namely, Zenker, Flemming, Kihara, Navashin, and Allen's Bouin upon *Matthiola* ovaries, favoured my fixative both in regard to penetration and spreading of the chromosomes. For *Pisum* pollen mother-cells, whole buds are fixed in Carnoy for about 30 seconds; the Carnoy is then poured off and the fixation continued in the above fixative. This method is similar to Kihara's.

Although not used extensively on pollen mother-cells, the fixative has given good preparations by the smear method. The following, however, was found better for *Matthiola* pollen mother-cells:

1 per cent Chromic acid	90 c.c.
Potassium bichromate	3 gm.
Sodium sulphate	1 gm.
Urea	1 gm.
2 per cent Osmic acid	20 c.c.
Distilled water	50 c.c.

A third fixative used successfully with the smear method for pollen mother-cells is a mixture of Allen's Bouin and Champy in equal proportions. This was found useful for *Campanula* and *Solanum* species. The smeared slides, after washing and taking up through alcohols, must be left from two to three hours in a saturated solution of lithium carbonate in 70 per cent alcohol to remove any remaining picric acid.

L. LA-COUR.

An Isotope of Carbon, Mass 13.

THE bands belonging to the Swan spectrum of carbon appear in the vacuum electric furnace at about 2400° C. At temperatures above 2600° they are strong and clear-cut, even the band at λ6191, difficult to obtain in the carbon arc, being well defined. It has been noted by one of us, during a variety of electric furnace investigations, that plates on which the band at λ4737 is very strong showed a faint band, not to be ascribed to a ghost, about 7·5 A. to the red of the strong band. The carbon arc shows a scattered structure in this region, which is suppressed in the furnace. It has, however, thus far failed to give the faint band, which in the furnace spectrum shows a distinct structure, essentially identical with the structure of the main band.

The recent discovery of isotopes of oxygen makes it very probable that other similar elements contain isotopes in small quantities. We have accordingly measured this faint band very carefully, using a first order exposure of a 15 ft. concave grating, the furnace being at about 2800° C. It is now generally agreed that the Swan bands are due to the neutral C_2 molecule, presumably $C^{12} - C^{12}$. We find that the new faint band corresponds quantitatively to that which should be given by an assumed $C^{13} - C^{12}$ molecule. The constants of the Swan band system are known with great precision ("Int. Crit. Tables", **5**, 411, and J. D. Shea, *Phys. Rev.*, **30**, 825; 1927), and an accurate comparison with theory is therefore possible. With data of the precision now becoming available for oxygen, as well as in the present case, it is necessary to avoid various approximations which have commonly been used in previous work on isotopes. This will be fully discussed in later publications.

Because of irradiation due to the strong band, it is to be expected that the measured distance between the two *heads* will be slightly *smaller* than the calculated isotope shift for the head. This is in fact the case, this distance being measured as 2·020 mm. (= 7·520 A. = 33·44 cm.$^{-1}$) as compared to a calculated isotope shift of 2·028 mm. (33·58 cm.$^{-1}$). Fortunately, however, it is possible to distinguish six individual lines in the very faint isotope band. These have been identified as the unresolved triplets P_{26} to P_{31} (Shea's nomenclature). In the comparator P_{30} and P_{29} could be measured with reasonable accuracy, P_{28} and P_{27} less reliably, P_{26} very poorly, and P_{31} not at all. The corresponding triplets in the main band (also unresolved) could be measured with great precision. The observed isotope shifts in millimetres for P_{30} to P_{26}, with the calculated in parenthesis in each case, are 2·059 (2·0515), 2·049 (2·0473), 2·037 (2·0429), 2·033 (2·0395), and 2·044 (2·0373) respectively. Multiplication by 16·58 gives the shift in cm.$^{-1}$. The two good lines (P_{30} and P_{29}) give an average measured shift 0·082 cm.$^{-1}$ too large. Although with the present available data the fact may have no significance, it is interesting to note that this small discrepancy may be cancelled by assuming 12·0000 and 13·0026 for the two masses.

This 1-0 band (λ4737) is especially favourable for showing the faint isotope molecule, when one considers photographic intensity, position with respect to other bands (particularly CN), and size of the shift. We shall endeavour to get better plates, showing the isotope effect in other bands, and also showing more detailed fine structure. The present evidence seems, however, fully sufficient to establish the existence of an isotope of carbon, of mass 13. We cannot at this time make any statement as to its relative abundance, except to say that the isotope band is hundreds of times as faint as the strong band.

A Spinning Target X-ray Generator.

IT is a well-known fact that the energy density, that is, the energy per unit time and area in the focus of an X-ray tube, cannot be raised indefinitely owing to the extreme heating and consequent deterioration of the target surface. The input limit has been calculated for the usual type of X-ray tube in a previous paper (*Proc. Roy. Soc.*, A, vol. 117, p. 30; 1927).

In many applications of X-rays it would be very valuable to work with higher energy densities than those which had been used so far. This requires a method of removing the heat more radical than has been hitherto adopted. A simple way for doing this is

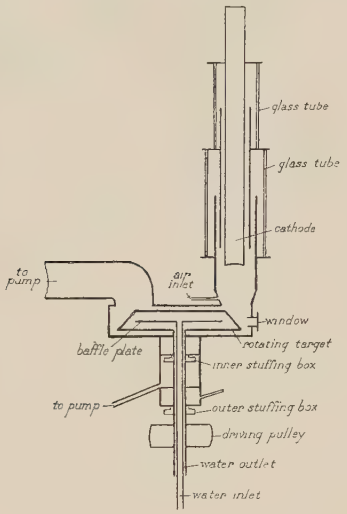

FIG. 1.

to produce the focus on the periphery of a rotating disc. The theoretical discussion which will shortly appear shows that the input limit can be raised as follows:

$$W_{\substack{\text{max.}\\\text{rotating}}} = W_{\substack{\text{max.}\\\text{rest}}} \times \sqrt{\delta \cdot \frac{\rho \cdot c}{k} \cdot v}$$

where $W_{\substack{\text{max.}\\\text{rotating}}}$ = maximum input for a rotating target, $W_{\substack{\text{max.}\\\text{rest}}}$ = maximum input for a target at rest, c specific heat of the anticathode material, k thermal conductivity, ρ density, δ radius of the focus in cm., v velocity of the target at the focus. This equation only holds if the expression under the square root is large compared with unity.

The use of the rotating disc avoids excessive local heating, but it is still necessary to remove the heat from the cathode as a whole, and this can be done by a water-cooling system.

An experimental X-ray plant embodying these principles of design has been built in the Davy-Faraday Laboratory. The target of the generator as shown in the diagram (Fig. 1) consists of a hollow copper disc with a bevelled surface on which the cathode rays impinge at about 5·5 cm. distance from the centre of the disc. The disc is mounted on a hollow shaft and rotates with about 2000 rev. per min. The cooling water is fed into the hollow target through a small tube inside the shaft and is directed against the inner cooling surface of the target by a baffle plate. The outlet is formed by the concentric space between the inlet tube and the inner wall of the driving shaft. The generator is permanently connected to a high-speed pump, and the pressure is regulated by a needle valve. The maximum input which the generator should stand according to calculations is about 5 kilowatts with a focus of 1 mm. diameter.

The generator was first tested on a high-tension plant which consisted of two large induction coils capable of standing an input of more than 20 kilowatts and operated by a specially constructed Wehnelt interrupter. The peak potential, judging from the spark gap, varied between 30 and 100 kilovolts. On one occasion, the input in the primary circuit being then about 30 kilowatts, a groove was cut in the disc of about 1 mm. width showing that a sharp focus must have been obtained in this experiment. Measurements of the actual energy striking the target were not made in this preliminary test. The X-ray energy must have been considerable, and visual observations of powder rings and of patterns due to reflections by a single crystal could be made on a fluorescent screen quite easily.

A second test was carried out at lower voltages, using this time a completely rectified supply. The generator ran very steadily at 25,000 volts and 100 milliamperes; at 19,000 volts and 200 milliamperes the discharge began to be unstable. This was possibly due to the heating of the cathode, the cooling of which depended entirely upon radiation in these preliminary tests.

I have been assisted in this work by Mr. R. E. Clay. A detailed description of the generator will be given later. I wish to express my thanks to the G.E.C. Research Laboratory in Wembley for letting me use their large high-tension D.C. plant.

The Origin of Variations.

AN article by Sir Oliver Lodge, dealing with the extracts from the Hooker Lecture on "The Origin of Adaptations" which were published in the issue for June 1 (p. 841), appears in the issue for June 29 (p. 982). It is very gratifying that the lecture has aroused the interest of so distinguished a physicist, and I can assure him that all biologists will welcome his intervention and value the analysis of their problems to which he has given expression. With much of his article I am in full agreement, and for the rest, two quotations will perhaps most briefly make my position clear. The first has appeared on the title-page of every issue of NATURE since its first number was printed in 1869:

"To the solid ground
Of Nature trusts the mind that builds for aye."
—WORDSWORTH.

The second, in lighter vein which Sir Oliver Lodge with his keen sense of humour will appreciate, is from Prof. Eddington ("The Nature of the Physical World", p. 21):

"It does not seem a profitable procedure to make odd noises on the off-chance that posterity will find a significance to attach to them."

The course deprecated by Prof. Eddington seems to be the very one which Sir Oliver Lodge advises biologists to follow. With Wordsworth's lines he will, I imagine, be willing to express agreement, and they have this advantage that, perforce, he must abstain from making square-bracketed insertions which would upset the poet's rhythm, to say nothing of changing his meaning.

E. J. ALLEN.

Marine Biological Laboratory, Plymouth.

In a stimulating article in NATURE of June 29, 982, Sir Oliver Lodge makes the following statement: We know, however, that [germ-plasm] is modifiable y slight changes in environment." Apart from the uestion whether we can in reality separate germ-plasm rom soma, and excluding cases of injury, I suggest hat we do not know this. Do we even know for cer-ain that the soma itself can be changed ?

In a few cases it is claimed that changes in soma ave been brought about by an alteration in environ-ient, and even that those changes are capable of being ransmitted from parent to offspring. Without ttempting to touch upon the question of the inherit-nce of acquired characteristics, I would yet point out hat for every single case where environment has been ntentionally changed and its effect noted, there are housands of cases in Nature where change of en-ironment has failed to produce any apparent modi-ying effect.

Personally, I do not think that there is much diffi-ulty in accounting for the absence of the influence of hange in environment, for I believe that any such nfluence can be selective only. Environment may be ll-important as a selective influence, but as such that nfluence must be definitely restricted. Perhaps this onception may be made clearer by reference to a mple concrete example. Given an ordinary dice, ne can turn it up several ways and thus select several umbers, but they can only range from one to six. iven the power of changing the numbers, however, nd the range of selection becomes infinite. No one ould deny the selective influence of environment, but believe that its *modifying* influence has yet to be emonstrated.

Production of High Lo Surdo Fields.

IT has already been reported in this journal (NATURE, ug. 25, 1928, p. 277) by one of us, that the field trength in a Lo Surdo tube may be increased con-

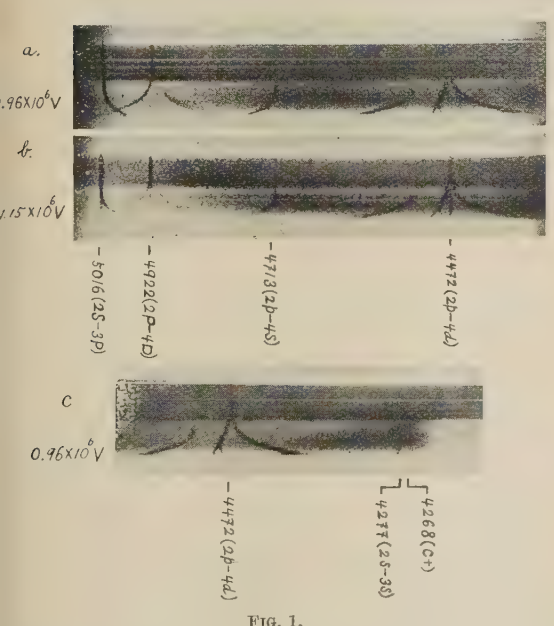

FIG. 1.

derably by the simple device of using proper periodic npulses as the terminal supply. Since then the xperimental arrangement has been improved so that a steady discharge may be maintained in a capillary tube the inner diameter of which is as small as 0·5 mm. for two or three hours. First, the volume of the discharge tube was increased to more than 20 litres; and secondly, only the half wave was used by taking off some of the vanes of the synchronous motor rectifier. Finally, the induction was removed from the secondary circuit. In this way the maximum voltage attained was roughly 1·2 million volts per cm.

The accompanying photographs (cf. Ishida and Kamijima: Sc. Pap. I.P.C.R. **9**, p. 118) were taken by a small Fuess spectrograph. The undeflected lines in photograph *b* are the superposed zero lines. The following points may be noted:

1. The lines λλ5016 and 4922, which barely touch each other at a field of 550 kv., here cross decidedly.
2. The shorter wave component of the line λ4472 turns back to the zero line in photograph *b*, whereas the longer wave component keeps its original direction.
3. The line λ4268 of ionised carbon is deflected to the negative side.

Chemical Research, Tokyo, Japan.

New Bands in the Spectrum of Oxide of Lanthanum.

A SMALL portion of the spectrum of oxide of lanthanum has been known for some time. The most notable of the old measurements (v. Kayser, "Handbuch der Spektroscopie", Bd. 5, p. 666, Leipzig, 1910) refer to two groups of bands in the violet at λ4418 and λ4372, and to a pair of bands in the green at λ5600 and λ5626.

R. Mecke (*Naturwiss.*, **17**, 86; 1929) identified and measured seven groups of bands recently at λλ4372, 4418, 5600, 7380, 7403, 7877 and 7910, and Auerbach (*Naturwiss.*, **17**, 84; 1929) identified other bands in the spectrum between λ7876 and λ8638.

The spectrum of oxide of lanthanum has usually been obtained by means of the electric arc; Hartley was the only one who used the oxyhydrogen flame. But the spectra so obtained are incomplete because the necessary conditions in order to volatilise perfectly the oxide of lanthanum have never been attained. It either decomposes almost completely into metal and oxygen, or it remains partially as a very fine powder.

By means of a simple arrangement of the oxy-hydrogen flame, I have been able to vaporise the oxide completely. The spectrum emitted in this state shows bands only; there are no lines or continuous background.

The spectrum has been photographed with a quartz spectrograph between λ7000 and λ2400, and shows groups of bands at λλ6540, 6154, 5866, 5600, 5380, 5178, (5058), 4582, 4543, 4531, 4418, 4372, 4357, 3708, 3671, 3620, 3612, 3566. The groups between λ6540 and λ5058 are all composed of double-headed bands; the separation of the double heads decreases from group to group as the wave-length decreases.

It is interesting to note that the presence of various bands in the ultra-violet region of the spectrum has now been established; their existence had been predicted by R. Mecke as the result of his investigation of the bands in the green and red.

Recent Progress in Canadian Hydro-Electric Power Development.

By Dr. BRYSSON CUNNINGHAM.

IT is just about two years (*vide* NATURE, Aug. 27, 1927, and Sept. 3, 1927) since, on my return from a round of visits to some of the principal waterfalls and generating stations in eastern Canada, I described the situation in the Dominion as regards the development of its water resources for power purposes. It will probably be of interest at this stage to recount the progress which has been made during the intervening period, particularly as it continues to be of a very notable and far-reaching character. The statistics used for the purpose and the tabular information incorporated in this article have been derived from recent reports issued by the Water Powers Branch of the Canadian Department of the Interior.[1]

In order to appreciate fully the importance of water power development in Canada, it is necessary at the outset to bear in mind two salient facts; first, that the Dominion as a whole, and particularly its two chief industrial and manufacturing provinces, Quebec and Ontario, are very favourably endowed with abundant natural sources of water power; and secondly, that these same two provinces are singularly lacking in geological deposits of coal. Distinguished as the Acute Fuel Area, the two provinces, comprising the bulk of the population and the predominant share of commercial, mining, and manufacturing interests, would be lamentably crippled in their activities were it not for the fortunate compensation. Water power, therefore, is an essential feature of the industrial development of the Dominion.

In Great Britain, developable water power supplies are relatively meagre and of an insignificant order. Estimates of the aggregate are somewhat varied and range up to a million horse-power or perhaps slightly more. In Canada, although there are important regions incompletely surveyed and imperfectly scheduled, fully forty million horse-power is now definitely located and accounted for, and of this about 5½ million h.p. has been actually developed up to the present time. It is true that the developed horse-power amounts to little more than 13 per cent of the estimated available total, yet it is greatly in excess of anything realised or even realisable in Great Britain. Moreover, it is steadily increasing at a rapid rate. Less than five years ago the total of developed horse-power was only 3½ millions; nine years ago, 2½ millions; and in 1900, less than a quarter of a million. If we take the rate of progress (nearly 500,000 h.p. per annum) which has obtained during the last five years, another decade will suffice to see more than ten

FIG. 1.—Hydro-electric installation (540,000 h.p.) at Isle Maligne, Lake St. John, Province of Quebec. (By courtesy of the High Commissioner of Canada.)

[1] No. 1227, Water Power in the Mineral Industries of Canada. No. 1231, Water Power in the Pulp and Paper Industry of Canada. No. 1242, Hydro-electric Progress in Canada during 1928. No. 1253, Water Power Resources of Canada.

illion horse-power in operation. Fig. 1 illustrates single development of 540,000 h.p. carried out thin a period of five years.

From the economical point of view, the present hievement and its future possibilities are specially oteworthy. It has just been pointed out that the ovinces of Ontario and Quebec, covering an area well over a million square miles, are practically stitute of internal coal supplies, and are dependent external sources for mineral fuel. On a reason-le computation under existing conditions, each stalled water horse-power is the equivalent of tons of coal per annum. This means that at e present time there is a saving in coal consump-554 per thousand. In certain provinces the ratio is much higher; for example, in British Columbia it is 952, and in Quebec 902. In Yukon and the North-West Territories, where the population is scanty and there are heavy demands for power for low-grade gold mining, the figure is as high as 1039.

Perhaps a fairer and more apposite comparison would be with the United States, where, reduced to the same basis of computation (ordinary six months' flow and 80 per cent turbine efficiency), the developable horse-power may be put at about 60 millions. The quantity actually developed at the present time is $13\frac{1}{2}$ millions, equivalent to 127 per thousand of the population.

Fig. 2.—Two hydro-electric power stations on Gatineau River, Province of Quebec. Farmers' Rapids (120,000 h.p.) in foreground; Chelsea Dam (170,000 h.p.) beyond. (By courtesy of the High Commissioner of Canada.)

n in Canada of no less than 33 million tons—a narkable quantity. In districts with coal readily ainable by mining, the consideration to industry significant enough; where coal has necessarily be imported, it is vital.

The only European countries which compare h Canada in intensity of water power develop-nt per head of population are the Scandinavian gdoms and Switzerland. Norway, Sweden, and tzerland are each much smaller in area, have aller populations, and are less industrially loited. In the return published by the U.S. logical Survey in January 1927 (the latest res which I have at hand) the developed er horse-power of Norway is given as 717 per usand of the population, of Sweden as 223 per usand, and of Switzerland as 476 per thousand. the present time the average for Canada is

Table I. below shows the available and developed water power in the respective provinces of the Dominion of Canada as determined to Jan. 1, 1929. Compared with the similar table to January 1927, published in Nature in August 1927, there is an increase of nearly two millions in the available 24-hour horse-power at ordinary minimum flow, of more than one million horse-power for the same 24-hour period at ordinary six months' flow, and of rather more than three-quarters of a million in the horse-power of actual turbine installations. It will be noted that the provinces of Ontario and Quebec possess more than 60 per cent of the available power and more than 80 per cent of the installed power.

Comparison of the corresponding figures for available horse-power at ordinary six months' flow with those of turbine horse-power at sites where

generating plant is actually installed, shows the turbine installation to be 30 per cent in excess of the scheduled available quantity, and this has proved to be good commercial practice. Hence, it is reasonable to apply a similar percentage

addition to the total of 33,113,200 at the foot of column 3, bringing it up to about 44,000,000 and justifying the use earlier in this article of the estimate of "fully 40 million horse-power" as definitely located up to the present.

The figure of 5,349,232 given as the total turbine installation horse-power to Jan. 1 last takes no account of a number of large installations which were nearing completion about that date, or of a number of others which were in the initial stages of development. It is estimated that these uncompleted undertakings will add something like 1,200,000 horse-power to the total, and there is every prospect of further important enterprises being begun. For example, the Gatineau Power Company placed six large units of generating plant, each of 34,000 h.p. capacity, in operation at their Paugan Station on the Gatineau River in September last, with provision for two additional units of the same capacity. The same Company was simultaneously installing a fourth unit at each of two other stations lower down the Gatineau River, namely, at Chelsea and Farmers' Rapids (Fig. 2). These new units were so far advanced as to be expected to be in operation early this year. At Chute-à-Carron, on the Saguenay River, works are in progress for an initial installation of four units each of 65,000 horse-power, and these are under contract to be completed by July 1931, to be followed by additional units of an aggregate of about a million horse-power.

So much for the sources and extent of generation. It will be interesting now to consider the ultimate application of this vast accumulation of motive power. There are three main sources of absorption; first, the central electric station for general and municipal purposes; secondly, the pulp and paper industry; and lastly, miscellaneous industries, including mining. The first requires little or no comment. The central station is a characteristic and outstanding feature in modern civilisation; from it radiate supplies of electricity for domestic and street lighting, for power, heating, traction, and numerous uses of various kinds. The pulp and paper industry is Canada's chief manufacturing activity. The gross and net values of production and the disbursements in salaries and wages in this industry are greater than those of any other Canadian industry, while the national output of newsprint, that is, paper prepared for the newspaper printing press, during the last completed census year exceeded that of any other country. Some of the power required for the purpose is generated directly at the mills from a local water supply, in other cases it is taken by purchase from a central station; jointly, the quantity utilised in the industry is 25 per cent of the whole output of the Dominion. As regards the mineral industries, it can be said that the profitable operation of many

Canada	4,445,693	572,976	330,563	5,349,232	9,658,000	554

of the Canadian mines is only made possible by the low cost at which ample supplies of power can be obtained from hydro-electric sources. Fuel power would in many cases be prohibitive. It is affirmed in one of the Government reports that without the aid of water power the mining industry of Canada could not have approached its present magnitude.

Table II. shows, as at Jan. 1, 1929, the distribution of developed water power in Canada under the three heads detailed above. Column 2 in the table includes only hydro-electric stations which develop power for sale. Columns 3 and 4 comprise the power specifically generated for the industries in question. As explained above, additional and large supplies of power are obtained by purchase from the central stations.

It is interesting to note that the total outstanding capital invested in water-power developments represents an average of 219 dollars, or about £44 per horse-power installed, including transmission and distribution—quite a low figure compared with that of other countries under similar conditions.

Fully to describe and expound the striking figures collected and published by the Canadian Government would require much more space than can be allocated to the subject here. They are eloquent of vigorous progress and unflagging enterprise. To the ordinary reader they are full of interest; to the observant visitor they are a confirmation of impressions received from numerous striking spectacles; and to the scientific inquirer they open out a vista of wonderful possibilities for a country which is yet on the threshold of its career.

The Original Home and Mode of Dispersal of the Coconut.

By Dr. ARTHUR W. HILL, C.M.G., F.R.S.

THE origin and mode of dispersal of the coconut, which is now widespread throughout the tropics of the Old and New Worlds, has long been a subject of discussion. De Candolle, Beccari, Chiovenda,[1] and others consider the coconut originated in the Indian Archipelago or in the Pacific Islands, while O. F. Cook[2] attempts to prove that its origin was in the valleys of the Andes of Colombia in South America and that it was transported thence, entirely by human agency, far and wide across the tropic seas. H. B. Guppy[3] also holds the opinion that the home of the genus *Cocos* is in America, while Geoffrey Smith[4] states, on information given him by Mr. Hedley of Sydney, that the coconut was introduced to the Pacific Islands from Mexico by Polynesian mariners. Cook asserts that it is highly improbable that sea-borne coconuts could ever be cast up on a shore in such a favourable position that they could germinate without the aid of man, and Schimper[5] considers that the coconut groves "fringing most tropical coasts have only exceptionally originated without human aid". The fact remains, however, that coconuts are the common strand palms on almost every tropical island and that they were found well-established when many of these uninhabited islands were discovered.

Another fact which lends support to the original home of the coconut being the Indian Archipelago or Polynesia is the great variety of the coconuts now found in the East. Many of these varieties have well-marked characteristics such as colour of the nuts, thickness of the husks, etc., and many of these special kinds are grown specially for religious ceremonies among the Hindus, which also points to the palm being of great antiquity in South India. The hereditary occupation of the Tiyans of the Malabar Coast also is the tapping of coconuts for toddy.[6] Then, again, the Tamil and Malayalum name for the coconut is *tengai* (*ten* = south, *kai* = fruit), that is, the fruit which comes from the south.

Chiovenda[1] (l.c. pp. 397-399) quotes a reference to the coconut in Indian medical literature, supposed to date back to 1400 B.C., and a statement of Ctesia that coconut oil was in common use in India in 400 B.C. He cites evidence that the coconut was widely cultivated in the Gangetic Plain in the first century of the Christian era, and refers also to two Arabian travellers, Abu Said and Ibn Wahab, who in the ninth century went as an envoy to China and reported that the Laccadive and Maldive Islands were covered with coconut palms, which appeared to be indigenous there. One of these travellers also made the interesting statement of the existence in India of a religious sect, which, for humanitarian reasons, introduced and propagated the coconut on those islands where it did not already exist.

The name 'coco' appears to be due to the Portuguese,[7] and they were made acquainted with the palm from their voyages in the East. The commonest word in the languages of the Pacific for the coconut is some form of the Indonesian

[6] See Sampson, H. C. "The Coconut Palm", 1923, p. 74 *et seq.*

[7] "The Simples and Drugs of India", Garcia Da Orta (1563), translated by Sir Clements Markham, p. 139; also "Roterio", Vasco da Gama (1498) and the book of Barbosa (1516).

Garcia da Orta generally spells the name *coquo*: "We, the Portuguese," he writes, "with reference to those three holes, gave it the name of Coco (Spanish *macoco*, for monkey-faced), because it seems like the face of an ape or other animal." With regard to other names, he says the palm is called Maro and the fruit Narel, and this word Narel is common to all, for it is used by Persians and Arabs (*narikela* Sanskrit, in Persian *nargila*, a name given to the 'hubble-bubble', or Indian smoking stand-pipe, from the shell of a coconut being generally used to contain the water through which the smoke from the tobacco bowl is sucked through a long, flexible serpentine pipe; and *nari-kela* simply means 'water spring' or 'squirt').

"Avicenna calls it Jauzialindi, which means 'nut of India' (Jauzulhindi, the Indian nut). Serapio and Rasis call the tree Jaralnare, which means 'the tree that yields Coco' (Jaralnari, the Naril tree). The Malabar people call the tree Tengamaram (the Southern Tree, *i.e.* introduced from Ceylon), and the fruit when it is ripe Tenga. The Malays call the tree Tricam (Trinarajah, 'King of Grasses,' is a Sanskrit name for the coconut palm), and the coconut Nihor."

It is also of interest (l.c. p. 141) to note that the word 'coir' comes from the Malabar Kayiru, the fibrous rind of the coconut (see also Watt, "Dictionary of the Economic Products of India").

niur (*niu*, *nu*), and everything points to these names being of great antiquity, thus lending additional support to the coconut belonging to this part of the world. Mr. S. H. Ray, in a letter to me on the matter, suggests that the fact of the coconut having other names among the Papuan and Melanesian peoples and traces of others in Indonesia seems to point to it being indigenous in the Islands.

In connexion with the Polynesian Islands being the original home of the coconut palm, Beccari (l.c. pp. 804-806), lays stress on the occurrence of the robber crab, *Birgus latro*, in these Islands. This remarkable crab is able to break open the coconut shell with its heavy chelæ by hammering with them on the 'eye hole' until a large enough opening is made for it to insert its small chela in order to extract the pulp or endosperm.[8] It also ascends the palms for the purpose of getting the nuts, and is said to put its abdomen into the shell and carry it about with it as a protection. Another interesting point suggesting that the association of the robber crab and the coconut must be of great antiquity is afforded by the fact that the crab uses the husk of the nut for lining its burrows. Beccari considers this association of the crab with the coconut affords further support to the view that the coconut originated in the Polynesian region. Geoffrey Smith, however, does not believe the association of the *Birgus* with the coconut is of very ancient origin, possibly because he accepted the information given him by Mr. Hedley, that the coconut was introduced to the Pacific Islands from Mexico by Polynesian mariners.

Although there is this remarkable association between the crab and the coconut, it is only right to point out that the crab is found on islands where there are no coconuts and vice versa, also that the crabs are commonly found on the fruit clusters of *Pandanus*, the screw pine, the individual segments of which are much chewed and squeezed by the crab.

F. W. Christian[9] gives the names *kuku* from Rarotonga and the Gilbert Islands and *kukuma* in the Marquesas for the robber crab, and also quotes the Arabic *khukum* (a crab), and the Maori *kuku* (to nip). These names suggest a possible connexion with the Portuguese *coco*. Dr. C. O. Blagden, however, who has kindly looked into the matter, has sent me the following letter, which shows that there are no grounds for connecting the name 'coco' with any native names of the crab.

> On the face of it, it seems to me somewhat unlikely that the name of the cocopalm should have been derived from that of the land crab (or other crab), that preys upon it. Man is much more interested in the many uses he derives from the tree than in the crab; and the tree has, I imagine, a very much wider area of distribution than the crab.
>
> As a matter of fact, however, the name of the tree does not, as a rule, resemble that of the crab. Its most diffused general name in the eastern islands from Madagascar to the Marquesas, is *niur*. Other names, such as *kelapa*, *kelambir*, and the Celebesian *kaluku* (of which *Koekoe*, *i.e. kuku*, may be either the primitive or the reduced form), are more local.
>
> So, I should suppose, are such crab names as *kuku* and *kukuma*. In Malay and other Indonesian languages, such as Javanese, etc., there are two words:
>
> (1) *Kuku*, claw, hoof, nail (of finger or toe).
> (2) *Kukur*, claw, to claw, to rasp, probably variants of one word. (There is also a variant with a final *-t*, *kokot*, in some places.)
>
> In practically all parts of Polynesia, from Fiji to New Zealand, and Hawaii to the Paumotus, are found derivatives of either (1) or (2) or both, in the sense of 'claw, nail, hoof', or 'to nip', and the like. As these languages tend to drop final consonants, it is difficult to say whether such words belong to (1) or (2). But apparently they do not generally mean 'crab'. It seems reasonable to connect these words with the local names of the crab. Compare Malay *ketam*, 'crab', but also 'to nip', found in several languages from Sumatra to the Philippines.
>
> I do not think the Arabic *khukhum* can be more than a fortuitous case of resemblance. I do not know it.
>
> As for the relation of all this to *coco*, I fail to see how it can be accepted in view of the fact that the word occurs in Vasco de Gama's Roteiro (1498) and in the book of Barbosa (1516), both written before Europeans got far enough east to reach the region where the cocopalm or nut is called *kuku*. The word seems to be quite European (Portuguese and Spanish).

The coconut is of great antiquity in Ceylon, and the earliest mention of it, Mr. Stockdale informs me, occurs in the "Mahawansa" in the reign of Dutthagamani, 101–77 B.C. Hsüan Tsang (II, p. 252), who travelled during A.D. 629–645, refers to coconuts in the Island of Na-lo-ki-lo (=Narakira—coconut=? Maldives), and says, "The people of this Island grow no grain but live only on coconuts". The Government Archivist of Ceylon also informs me that Sinhalese taxes on coconuts were in existence in pre-Portuguese times and were called *Pol watta-piediya* and *Polaya-panam* (*Pol*=coconut in Sinhalese, *watta*=garden). In Yule and Burnell's "Hobson-Jobson", the passages quoted referring to the 'Argell' or 'Great Indian Nut', from Cosmas, the Monk, *circa* A.D. 545 or A.D. 547,[10] and others lend further support to its Old World origin.

As opposed to the theory of the Polynesian origin of the coconut, Chiovenda (l.c. p. 398 and p. 449) holds the view that it originated in lands, now submerged, somewhere in the north-west of the Indian Ocean. He refers to Reinaud's records of the Indian, Albirunhi, in the eleventh century, who mentions the submergence of land in the region of the Laccadive and Maldive Islands, and of how the people of these islands, when fleeing for safety, took their coconuts with them. He also refers to fossil Cocoineæ, related to *Cocos*, having been discovered in Central Europe.

The fact that the early explorers found the Coconut palm of very limited distribution in tropical

Supplement to NATURE

No. 3117 JULY 27, 1929

Africa and Science.

By JAN H. HOFMEYR, President of the South African Association.

INAUGURAL ADDRESS DELIVERED AT CAPE TOWN ON JULY 22 TO THE BRITISH AND SOUTH AFRICAN ASSOCIATIONS.

TO-NIGHT I enter upon the consummation of what is at once the highest and the least merited distinction which it has been my privilege to receive. To those who called me to the office of president of the South African Association for the Advancement of Science I tender my sincere thanks. I make myself no illusions in respect of the adequacy of my claims to that honour on the ground either of scientific attainment or of services rendered to the cause of science, nor would I have our visitors remain for a moment without the knowledge that my scientific qualifications for this presidential chair are of the slightest. They are far less indeed than those of that distinguished statesman to whom, when he had remarked to the great Faraday in relation to an important new discovery in science, "But after all, what is the use of it?" the scientist replied, "Why, Sir, there is every probability that you will soon be able to tax it."

The presidency of this Association is an honour the conferment of which upon myself has never seemed to fall properly within the scope of my ambitions; it imposes responsibilities for the discharge of which I am all too scantily equipped; and I can only seek to justify my election in a manner similar to that which Mr. Stanley Baldwin followed when he was chosen to be president of the Classical Association in England. I can but say that, while it is to the scientist that we look for the advancement and the progress of science, the effectiveness with which his work is brought to fruition does depend in some measure on the interest, the sympathy, and the enthusiasm with which his achievements are followed up by that army of plain, ordinary men, in which I gladly count myself a musket bearer. In no other capacity dare I venture to address you. It was once said by a literary man of some distinction that the man of science appears to be the only man in the world who has something to say, and he is the only man who does not know how to say it. There is an obvious rejoinder, that the man of letters frequently has nothing to say, but says it at great length. I dare not claim to be a man of science. I can only hope that I shall not be deemed to have qualified for consideration as a man of letters in the sense of that retort.

The honour which has been conferred upon me is the greater because of the special significance which attaches to my year of office. It is the year of the keenly anticipated second visit of the British Association for the Advancement of Science to South Africa, and for that reason my first words are, happily, words of welcome. Not merely the Association for which I speak, but also all South Africa, rejoices in the presence of the British Association and its distinguished members. To its parent body, which can look back upon all but a century of glorious achievement, this stripling Association brings its tribute of respectful admiration and goodwill. To the great organisation of scientific men, the history of which is the history of the advancement of science in Britain, which has a presidential roll adorned by names such as Brewster and Tyndall, Huxley and Kelvin, Rayleigh and Lister, this land of ours, mindful of its debt to science, conscious of the gifts that science can yet bring to it, extends the hand of friendship, in gratitude for the honour of this visit, and in appreciation of the stimulus to its progress and development which must needs attend it.

We have reason, indeed, to be grateful to the British Association for its achievement and its significance. If I might select three distinctive features in its record, they would be these. First,

its contribution, direct and indirect, to those great triumphs of British science in the nineteenth century which are the possession not of an age, or of a nation, but of all time and of every land. Directly it has initiated, correlated, and contributed towards work of great scientific value; indirectly it has inspired much constructive activity, while its meetings year after year have done more than any other single factor to stimulate and hasten the onward march of science.

Next I would dwell on its maintenance of a broad view of the scope and function of science, and, coupled with that, the emphasis laid by it on the essential homogeneity of science conceived thus broadly, and the interdependence of its several branches. The Association had no lack of opposition to encounter at its coming birth. Those who interpreted science primarily in the medieval sense as being limited to the sciences of introspection had still but scant respect for the claims of the sciences of observation. When in the second year of its existence the Association visited Oxford, Keble protested vigorously against the University's reception of what he called a hodge-podge of philosophers. This hodge-podge, be it noted, included Brewster and Dalton and Faraday. But the Association did not react into narrowness. It remained true to the broad conception of *Scientia* which was held by its founders, one of whom affirmed in striking language at the first meeting, that "The chief interpreters of Nature have always been those who have grasped the widest fields of inquiry, who have listened with the most universal curiosity to all information, and felt an interest in every question which the one great system of Nature represents".

The Association has imposed no narrow restrictions on the extension of the sphere of its activity; within that ever-widening sphere it has maintained a spirit of co-operation between workers in diverse fields which has been worthy of the best traditions of Francis Bacon. It has had its reward—in greater effectiveness of work in its own sphere, and in the permeation of the kingdom of learning with the atmosphere of goodwill. By way of illustration of this last point, may I, as one whose first allegiance is to the classics, mention the fact that the roll of twenty-six presidents of the Classical Association of England includes five fellows of the Royal Society, names such as Geikie, Osler, and D'Arcy Thompson, and if it is not too presumptuously personal to refer to it, I would add, that when the South African Association elected me as its president, it chose one who was then president of the Classical Association of South Africa.

Lastly, I would select as characteristic of the British Association its success in maintaining the contacts of science with the public on one hand and the State on the other. One of the aims which its founders set forth was "to obtain more general attention for the objects of Science"; they sought to create a body which would make its appeal to the educated public as a whole, to fashion an instrument for the interpretation of the sometimes highly technical results of scientific investigation to the man in the street. They realised that the scientist received much from the public, that to the public he must freely give, and that the giving would not be without its due reward of new inspiration and renewed enthusiasms. There were some who opposed the nascent Association in the fear that science might degrade itself by making too popular an appeal. That fear has been belied in the passing of the years. The Association has kept touch with the public, it has "demonstrated to all men that science is thinking with them and for them", it has secured their interest and their sympathy, but it has never paid for that achievement the price of a lowering of its aims or of its standards. It is its success in this respect that has secured for it the prestige which has enabled it time and again to stand forth as the ambassador of science to the State, and so to play an important part in initiating and furthering enterprises of great national and scientific significance.

For these reasons and for much else, South Africa is proud and happy to be able to welcome and do honour to the British Association for the Advancement of Science. We welcome it the more heartily because of our consciousness of the greatness of our indebtedness to the first visit of the Association twenty-four years ago. To that visit, with which there will always be linked a name honoured in the history of South Africa, as it is in the annals of science—I refer to Sir David Gill—this country still looks back with grateful recollection. It marked the commencement of an epoch in our scientific history, the epoch of the consolidation of the position of science in South Africa.

Progress of Science in South Africa.

Let us view the position of science in our country as it was in 1905. On the academic side it is the nakedness of the land that chiefly impresses us. South Africa then had but one university, and it was in reality only a board of examiners for the

candidates presented by various colleges, which were all, without exception, inadequately staffed and poorly equipped. In the subjects which fell within the scope of the Association, as it was defined in 1905, there were in all the colleges taken together in that year only forty-nine workers, thirty-three professors and sixteen others. When it is remembered that this was the total number of teachers of all branches of science spread over seven different institutions, all purporting to do university work, it is painfully obvious how little time was available for scientific research and investigation. Nor was the work done, measured in terms of the number of graduates, very impressive. The number of those who in 1905 qualified for degrees in pure and applied science was only twenty-seven.

Outside of the colleges, scientific workers were to be found mainly in government departments, then still small and inadequately staffed, and working in isolation in the four South African colonies. In most branches the State's scientific activities were still in their earliest infancy. The organisation was only just commencing to be built up. As part of these activities there fall to be mentioned the two astronomical observatories at that time in operation: the Royal Observatory at Cape Town, then already full of years and of honour, and the Johannesburg Observatory, which, thanks largely to the representations made by this Association of ours, had been established a few months before the 1905 meeting.

In regard to scientific societies there is but little to record. There was in existence in 1905 a small South African Philosophical Society (now known as the Royal Society of South Africa), the Geological Society of South Africa, the Cape Society of Engineers, the Chemical Metallurgical and Mining Society, and also this Association for the Advancement of Science, which had come into existence a bare three years previously. It was, indeed, the day of small things, and small also was the achievement which science in South Africa at that date had to its credit. If one leaves out of account the work of Sir David Gill and the scientific endeavour which had been put into the development of the gold-mining industry of the Witwatersrand, there is little indeed of permanent significance that remains.

Against this picture it is appropriate to set the picture of South African science as it will unfold itself to our visitors to-day. They will find three vigorous single-college teaching universities, which have in recent years made remarkable progress in the attainment of the standards of similar institutions in older lands, and also a federal university with six constituent colleges, which, like the single-college universities, are, in human and material equipment and in the output of the results of scientific investigation, very far ahead of their predecessors of 1905. Against the forty-nine workers of 1905 we can now set 429—134 professors and 295 others—within the range at present covered by the activities of this Association. The twenty-seven graduates of 1905 increased to 275 in 1928.

To the scientific societies of 1905 there have been added, since the last visit of the British Association, the South African Institute of Electrical Engineers, the South African Institution of Engineers, the Cape Chemical Society, the South African Chemical Institute, the Botanical Society of South Africa, the South African Biological Society, the Astronomical Society of South Africa, the South African Geographical Society, and the South African Economic Society, and this Association of ours has become an active, vigorous, and powerful body, proud of the achievements which it already has to its credit, challenging eagerly the tasks that await it in the future. The two observatories of 1905, our visitors will find, have increased to six, including the Smithsonian Solar Observatory in South-West Africa, and the equipment of these institutions includes four great telescopes, with objectives of 27 inches, 26½ inches, 26 inches, and 24 inches respectively, to which will shortly be added a 24-inch refractor and a 60-inch reflecting telescope—surely a remarkable astronomical equipment for so young a country. The stimulus of the 1905 visit, in which so many prominent European astronomers participated, has indeed borne rich fruit in the advancement of astronomical work in South Africa.

Perhaps our visitors will be impressed not least by the development and consolidation of the scientific departments of our Civil Service, by the magnificent Institute of Veterinary Research which the State has created at Onderstepoort and the effective work which through its scientific officers it is doing for the development of South Africa, and by the remarkably efficient and well-equipped Institute for Medical Research at Johannesburg, the credit for the establishment and maintenance of which falls jointly to the Government and the mining industry. Significant also of the attitude of the State to science, and full of promise for the future, has been the establishment of a Research Grant Board, which advises the Government on the practical measures necessary for the encouragement

of scientific research in the Union, and acts as its agent in the distribution of grants in aid of individual investigations.

Nor have we reason to be ashamed of the positive achievements of science in South Africa during the past quarter of a century. Most impressive, perhaps, regarded cumulatively, have been the advances made in our knowledge of the diseases of plants, animals, and men, and of the methods of preventing them. In 1905 we knew practically nothing of the plant diseases of South Africa. In that year the first steps were taken towards their scientific investigation. To-day a general survey has been completed, most of the important diseases have been worked out, and a highly efficient service for combating them is in operation. In 1905 also the Transvaal Crown Colony Government voted £1500 as a first instalment towards the establishment of a laboratory for the investigation of stock diseases. From that has sprung the magnificent body of work in veterinary science which has won world-wide recognition for the Onderstepoort Institute which I have already mentioned. More recently there has been founded the South African Institute for Medical Research, to which is allied the Miners' Phthisis Medical Bureau. The researches conducted there in the control of pneumonic infection, and the advances made in industrial hygiene in the fight against silicosis, have brought great lustre to these two institutions and to South Africa.

In other fields also South African scientific workers have won recognition. In geology, marine biology, the mathematical theory of determinants, the economics of gold production, and along several other lines of investigation, important scientific work has been done in South Africa ; a succession of discoveries has been made throwing light on the origins of the human race ; and applied science has by means of the conquest of distance in this far-flung land of ours, and of the construction of important irrigation and other engineering works, contributed generously to South Africa's progress. It may, perhaps, be taken as a measure of the achievement of science in South Africa in one of its aspects that, while in 1906 the value of products of the land exported from South Africa amounted to £5,928,000, the corresponding figure for 1927 was £27,815,000.

If I were asked to select the most broadly significant feature in the development of science in South Africa since 1905, however, I think I would pick out what one might describe as its South Africanisation. In 1905 science in South Africa was in large measure exotic. The workers had come almost exclusively from other lands. They were only beginning to apply themselves to our South African problems. In many cases they had not yet acquired a South African background, or a South African outlook. In the years that have passed South Africa has claimed those workers for her own, and they have given themselves to her service. They to whom this is the land of their adoption, no less than those to whom it is the land of their birth, and whom they have taught and inspired, have made it the land of their vigorous and devoted service. In its personnel, science in South Africa has become essentially South African ; and science has given itself with enthusiasm to the problems of South Africa. It has emphasised the specific contributions of South Africa to the wider problems of science, it has applied itself to the removal of those obstacles which hamper the material development of South Africa, it has taken up vigorously the study of South African economics and sociology and anthropology. Perhaps also one may claim that it has brought to bear on scientific investigation what we regard as the distinctive features of the South African outlook—freshness and breadth of view, receptivity to new illuminations, and readiness to see old truths in new settings and in the light of their wider bearings. Is it not South Africa that has given to science and the world the conception of holism ? And there is surely no gift more worthily representative of the South African outlook at its best that we could have offered. It may indeed be that that very South Africanisation of our South African science of which I have been speaking is but another instance of the holistic principle at work.

As I speak of the South African outlook in science, I cannot but direct attention, with that deep appreciation which I know we all feel, to the masterly address which four years ago General Smuts delivered from this chair, when he demonstrated in so compelling a manner (I quote his own description of the task he set himself) " that there is something valuable and fruitful for science in the South African point of view, that our particular angle of vision supplies a real vantage point of attack on some of the great problems of science ; and that, so far from the South African view-point being parochial in science, it may prove helpful and fruitful in many ways to workers in the fields of scientific research and investigation ".

Science in South Africa, then, has made itself truly South African, and in doing so it has established itself in the admiration and affection of the

people of this land. As a nation we are grateful to our scientists for their contributions to our intellectual and material progress. The liberal policy of the State in supporting scientific effort we heartily endorse; the increase in the mental stature and the prestige of the nation which science brings to us we sincerely welcome. We are proud of our South African science, not least because we know that we can regard it as distinctively ours. But while our science has been South Africanised, we can rejoice that there is nothing narrow about its South Africanism. Were it otherwise, it would have been false to the spirit of science. In applying itself to the problems of South Africa, it has succeeded in attracting the attention of the scientific world to South Africa. In that address to which I have already referred, General Smuts emphasised the fact that recent events had drawn the eyes of the world to this land of ours as a rich field for scientific investigation. "The scope for scientific work", he said, "in this department of knowledge" (he was referring more especially to human palæontology, but his words are of wider applicability) "is therefore immense; the ground lies literally cumbered with the possibilities of great discoveries. . . . Science has in South Africa a splendid field of labour; other nations may well envy us the rich ores of this great 'scientific divide' which is our heritage." Those words are well worth remembering. We speak sometimes of our wealth in South Africa—mineral wealth, agricultural wealth, potential industrial wealth—but great also is our scientific wealth, and great is the debt we owe to South African science for what it has done to reveal that wealth to ourselves and to the world.

There, then, in brief outlines, all too imperfectly drawn, is a picture of South African science in 1929. Contrast it with the picture of 1905, and you have the measure of the achievement of a great epoch. Science consolidated, science South Africanised, science recognised as of great national value, both in the spiritual and in the material spheres, science drawing to our country the eyes of the world—surely that is no unworthy achievement. As once more, after the lapse of many days, our Association makes its report to the parent body, to which it gladly pays the tribute of filial reverence, it does so with pride and satisfaction in the work of the intervening period, but also with grateful recognition of the inspiration which that visit of 1905 brought to South Africa as one of the constitutive factors in the progress of the last quarter of a century.

Leadership in Africa.

Now it has been our privilege to welcome this second visit of the British Association. Is it strange if we ask ourselves, as we gratefully remember the stimulus of 1905, what will be the stimulus of 1929? That visit had abiding results. What will be the results of this one? That visit inaugurated a new epoch. Are we not justified in believing that once again we stand on the threshold of a great advance? If that be so, what are to be the characteristics of the period on which we are now entering? What will be its achievement? In the period that followed the first visit of the British Association, we South Africanised science in South Africa. Is it too much to hope that in the next we shall Africanise it? Will not this visit perhaps give us the impulse and the inspiration to a bigger and a bolder enterprise? One of the most significant tendencies evidenced in South Africa in the last few years has been the growing consciousness of our obligations in relation to the continent of Africa. We have come to realise that the position of this European civilisation of ours set upon the verge of this great continent is a position of unique strategic importance, that it presents us with at once an opportunity and a challenge. While in the past we thought, as a nation, almost exclusively of our own problems and difficulties, we are now ceasing to limit our horizon by the Limpopo, we are beginning to envisage the task that awaits us beyond our own borders. In the mind of the nation there is being developed a new conception of South Africa, of a South Africa that consciously and deliberately seeks to play its part on the African continent, not aiming at conquest or domination, but never failing in its readiness to give its intellectual and material resources to aid all who are engaged in the task of developing this great undeveloped area of the earth's surface, which is so full of potentialities for the future welfare of the world.

If, then, South Africa aspires to leadership in Africa in other branches of activity, why not also in science? If the outlook of the nation is broadening, why should not its scientists also begin to think in continents? If as a people we are anxious to make our contribution to Africa, eager to give it of our best, rather than to get from it that which will be to our material advantage, why should not our science also become consciously and deliberately African in its outlook, its ideals, and the tasks to which it applies itself? If science has consolidated its position in South Africa, as

we believe it has, is it not fitting that, with South Africa as its base, it should enter now into the new sphere of opportunity and achievement which stretches mightily outwards from its borders ?

To our visitors I look to give us the stimulus and the encouragement to that enterprise. You have come to Africa. This great land-mass which has reared itself against time's passage, almost since time's beginning, and holds inviolate so many of the records of that passage, has challenged your attention. You have come to Africa to seek new inspiration for the study of the problems that interest you, by seeing them against a different background which has for many of you an unaccustomed vastness. But while Africa was your goal, you did not think fit to enter it at the point nearest to your homes. You steamed down, day after day, skirting the long coast-line of this vast expanse of veld and forest, and have entered it by its southern gateway. For a great body of scientists it is the only point of effective entry into Africa. It is by way of this southern gateway that science itself can most effectively be made to permeate Africa. To you, having so come, to you, the ambassadors of science, I present—Africa. It is Africa and science, which, I would like to think, are to-day met together. Happy indeed should be the fruits of the mating.

Africa as a Field of Scientific Endeavour.

It is to that theme—Africa and science—that I propose now to invite your attention. What can Africa give to science ? What can science give to Africa ? Those are the questions to which I would address myself. But as I speak, I would ask you all to remember that it is for the South African scientist that the answers to these questions have primary significance. It is for him that they have significance, because for the solution of many of the problems of South Africa a greater knowledge of Africa as a whole than is at present available is essential, and the extension of that knowledge is his personal responsibility. It is for him that they have significance, because he dwells in a land which is strategically placed for attacking the problems of Africa and for drawing forth its hidden resources of scientific discovery for the enrichment of science throughout the world.

What, then, can Africa give to science ? In reply to that I can do no more than suggest some of the lines along which Africa seems to be called upon to make a distinctive contribution to science.

First there are the related fields of astronomy and meteorology. To astronomy I shall but make a passing reference. This continent of Africa, more especially the highlands of its interior plateau, with its clear skies and its cloudless nights, offers wonderful facilities to the astronomer. As proof of the necessity of utilising those facilities, especially with a view to the study of the southern heavens, I need but quote the words used by Prof. Kapteyn on the occasion of the 1905 visit : "In all researches bearing on the construction of the universe of stars, the investigator is hindered by our ignorance of the southern heavens. Work is accumulating in the north, which is to a great extent useless, until similar work is done in the south." Africa has to its credit considerable achievements in the past in the field of astronomical research. The increased equipment now available should make it possible to increase greatly the amount of systematic work now being done, and to offer important contributions to astronomical science.

Probably of greater importance is the work waiting to be done in meteorology. Few branches of science have a more direct effect upon the welfare of mankind—that is a lesson which we in South Africa should have learnt only too well—but in few has less progress been made. In meteorological work Africa is probably the most backward of the continents. It is not so long since Dr. Simpson of the London Meteorological Office declared that, save from Egypt, his office received practically no meteorological information from the great continent of Africa. Moreover, the backwardness of meteorology is in large measure due to the intricacy of the problems involved, and the necessity of having world-wide information made available. The problems of meteorology are emphatically not the problems of one country or of one region. The South African meteorologist must see his problems *sub specie Africae* (the seasonal changes in South Africa depend on the northward and southward oscillations of the great atmospheric system overlying the continent as a whole) ; and quite apart from what he can learn from the rest of Africa, the Antarctic regions have much to teach him. But while the development of meteorological research throughout Africa is of supreme economic importance for Africa, Africa in its turn has its contributions to make to other continents. In particular should we not forget the close inter-relation of the meteorological problems of the lands of the southern hemisphere. The central position of Africa in relation to those lands gives not only special opportunities but also special responsibilities for meteorological observation and research. For the sake both

of South Africa and of science in general, I would venture to express the hope that this second visit of the British Association will give as powerful a stimulus to meteorology as did the first to astronomy.

Next, I would refer to Africa's potential contributions to geological science. Africa is a continent, portions of which have always had a special interest for the geologist because of the great diversity of the geological phenomena manifested, and the vast mineral wealth which, as its ancient workings so abundantly prove, has attracted man's industry from the very earliest times. But in our day the opportunities which it offers to the geologist to make contributions to the wider problems of science are coming to be more fully realised than ever before. Of special interest in this connexion is the light which African geology, more especially in the form of the study of ancient glacial deposits, can throw on the Wegener hypothesis of continental drift. In the past our geologists have thought mainly of the correlation of our formations with those of Europe. It is time that they paid more attention to their possible affiliations with those of the continents to east and west of us. If geology can establish the hypothesis that Africa is the mother continent from which India, Madagascar, and Australia on one side and South America on the other have been dislodged, it will give a new orientation to many branches of scientific activity. For that investigation also Africa occupies a central and determinative position in relation to the other continents, such as we have noted to be the case in the sphere of meteorology.

There are many other geological problems on which Africa can probably shed much light. There is, for example, the constitution of the earth's deeper sub-strata, in regard to which, as Dr. Wagner has recently pointed out, the study of the volcanic Kimberlite pipes, so numerous throughout Africa south of the equator, and of the xenoliths they contain, including the determination of their radium and thorium contents, may be of the greatest significance. There is the possibility that the exploitation of Africa's great wealth in potentially fossil-bearing rocks of presumably pre-Cambrian age will yet yield us remains of living beings more primitive than any yet discovered ; there are the great opportunities of study which the African deserts offer in the field of desert geology and morphology, and there is the assistance which African geology has rendered to vertebrate and plant palæontology, and can render to African anthropology in the investigation of this great museum of human remains and relics which we call the continent of Africa.

I pass on to medical science. I have referred already to the contributions to the study of the problems of industrial medicine and hygiene which the special circumstances of the South African gold-mining industry have made possible. Those contributions have, we may well hope, but prepared the way for advances of a revolutionary character in the early detection, prevention, and treatment of all forms of respiratory disease. But even greater are the opportunities which the continent of Africa offers for the study of tropical diseases, of which it may well be described as the homeland. In Africa there have been, and necessarily must be, studied the problems connected with malaria, blackwater fever, sleeping sickness, yellow fever, and many other scourges of civilisation, and from Africa there may well come hope and healing for mankind.

There are other problems of medical science for the study of which Africa is uniquely fitted. There are the physiological questions, important also from the political point of view, which bear on the fitness of the white races to maintain a healthy existence in tropical surroundings, at high altitudes, and in excessive sunlight. For these investigations the diversity of conditions prevailing in the various regions of the African continent make it a magnificent natural laboratory. There is the elucidation of the factors which account for the varying susceptibility of white and coloured races to acute infectious diseases, tuberculosis, and certain types of malignant disease, together with the light which such elucidation may throw on the physical and chemical composition of the human body.

Lastly, I would mention the exploration of that most interesting borderland between psychiatry and psychological science by an analysis of the mentality of the diverse African peoples. That investigation has an important bearing not only on the limitations and capacities of racial intelligence, but also on the methods which the ruling races in Africa should follow in seeking to discharge their obligations towards their uncivilised and unenlightened fellow-Africans.

Closely linked with medical science is the study of animal biology. In some instances the problems of the two branches of science are to be approached along parallel lines ; in others biological investigations are fundamental to the growth of medical science ; of no less significance is that unity which there is in Nature, making it possible for the truths of animal biology to be translated into

facts concerning mankind. In the African continent there is no lack of opportunity to advance science by physiological inquiries into animal structure, by the isolation of the parasites of human and animal diseases, and by the tracing of the life-histories more especially of the minuter forms of animal life. "Nowadays," in the words of Prof. J. A. Thomson, "the serpent that bites man's heel is in nine cases out of ten microscopic." But scarcely less important are the extensive facilities which Africa still offers for the study of the habits and behaviour of the larger mammals. The naturalistic study of these animals, not as stuffed museum species, but in the laboratories of their native environment, has received all too scanty attention from the scientist, and this is a reproach which African science, with its rich dowry of mammal and primate material, may confidently be expected to remove. Nor will this study of animal behaviour, especially of those animals which approach nearest to the human type, be without its bearings on our investigations of the workings of the human mind.

If in this hasty survey I may take time to mention one more point within this field, I would refer to the results which await the intensified activity of the marine biologist and the oceanographer in the as yet all but virgin territory of the African coast-line. This Association of ours has long dreamed of an African marine biological station as broad in its conception and comparably as useful from the wider scientific and the more narrowly economic points of view as those of Plymouth or Naples or Woods Hole, and withal a rallying point for the naturalist, the zoologist, the botanist, the geographer, the anatomist, the physiologist, indeed for all those workers whose diverse problems meet at the margin of the sea.

Origin of Man.

From animal biology we pass by an easy transition to anthropology, the study of man himself. Here Africa seems full of splendid promise of discovery that may verify Darwin's belief in the probability that somewhere in this land-mass was the scene of Nature's greatest creative effort. It would seem to be not without significance that Africa possesses in the chimpanzee and the gorilla those primate types which approach most nearly the form and structure of primitive man. To that must be added that in the Bushman, Pigmy, and negroid races Africa has at least two and possibly three early human stocks which are characteristically her own and belong to no other continent. No less striking is the fact that in Gibraltar, in Malta, and in Palestine, that is, at each and every one of the three portals into Africa from Europe and Asia in Pleistocene times, there have been discovered evidences of the presence of Neanderthal man. In Africa itself there was found at Broken Hill some nine years ago a skull with the most primitive or bestial facial form yet seen, and so closely akin to the Neanderthal stock as to establish firmly the expectation of finding further compelling evidence of a long-continued Neanderthaloid occupation of the African continent. The discovery at Taungs on one hand, which reaches out towards the unknown past, and the finds at Boskop and in the Tsitsikama on the other, which assist in linking up the period of Rhodesian man with the coming of the Bushfolk, open up to us, in conjunction with the aforementioned facts, a vista of anthropological continuity in Africa such as no other continent can offer. The recent investigations in the Great Rift Valley, near Elmenteita in Kenya, and the fossil discoveries on the Springbok Flats, north of Pretoria, have again fixed the attention of the anthropologist on Africa.

Nor are the data presently available restricted to these discoveries. The efforts of archæologists, and the application of improved scientific methods in excavation, are giving us stratigraphical evidence of the succession of stone cultures which is of the utmost importance. I have already mentioned the assistance which geology can render in this work, but there is needed also the co-operation of those who labour in the converging fields of anatomy, archæology, palæontology, and comparative zoology. That co-operation has already commenced. In the investigation of the Vaal River gravels it has yielded important results, and we may look forward to its continuance and expansion in the years that lie ahead. Of the importance of African anthropology for the understanding of that of Europe there can be no question. Work of importance has already been done in the study of the relations between palæolithic art in Europe and palæolithic art in Africa. The significance of these comparisons is but emblematic of the importance of similar investigations in regard to stone cultures, rock engravings, ancient mining, stone circles and ancient ruins, methods of primitive mining and agriculture, tribal organisation, laws and customs, indeed the whole range of the hitherto unexplained or partially explained phenomena of living and extinct cultures. There is no lack of avenues which the student of African anthropology may follow in the hope of finding at the end of them results of supreme value for science in general.

I would speak next of the vast field, as yet lmost uncharted, of phonological and philological udy. Here in Africa we have great opportunities r the examination of linguistic problems, and me of them have bearings which extend far beond the limits of Africa. One thinks first of the pportunities which Africa offers for investigating ie results of the transplantation of languages hich have a long history of cultural development ehind them to regions inhabited by primitive eoples. Here there are two sets of phenomena, ch with its own special interest. On one hand e have the modification of the languages of those uropean peoples who have established themselves Africa as permanent settled communities, under ressure of the new linguistic influences with which ey have been brought into contact. Of these henomena the study of Afrikaans offers perhaps ie best examples to be found in the whole field linguistics—its importance for the student of mparative philology is very far from being adeuately appreciated. On the other hand, we have ose cases where European languages have come Africa as the languages not of settled comunities, but of officials and others like them who e but temporarily domiciled in this continent, d leave no descendants behind them to carry on ie process of evolution of distinctive forms of eech. Here the phenomena which are of inrest to the student of linguistics are to be found the wealth of deformation and adaptation hich the native populations have introduced in eir endeavours to speak the European languages their rulers. Work such as has been done by chuchardt in Negro-Portuguese and Negro-French pens up a wide area of most attractive investiation.

The most important task in the field of African nguistics, however, is the actual recording of the ative languages in Africa, our backwardness in spect of which is a reproach to science. Such udy is, of course, important in relation to Africa self, but of even greater significance for my resent purpose is its bearing on scientific problems wider scope. In that connexion I would suggest vo points. We are still only at the beginning of ie study of comparative Bantu. That in due ourse should lead to a knowledge of Ur-Bantu. uch a study and such a knowledge will necessarily e of importance to the comparative philologist, oth because of the light shed by the study of one roup of languages on the study of other groups, nd also because it opens the way to the investigaon of the relationship of Bantu to the other African tongues, and its place in the general scheme of the languages of the world.

Of even greater interest is the study of African languages as throwing light on the interpenetrations and interactions of primitive peoples. Language is a function of social relationship, and its study is therefore of great value for ethnological and historical investigations. May I give one instance of what I have in mind? Two millennia back, south-west Arabia was the seat of the powerful commercial civilisations of the Mineans, the Sabæans, and the Himyarites, radiating eastwards to India and south-westwards to Africa. The extent of their relationship with Africa it has hitherto been most difficult to trace, but linguistic evidence may prove to be of great value. Prof. Maingard has pointed out to me that the Makaranga who live near Zimbabwe call water *Bahri*, a word closely related in form to *Bahr*, the 'sea' of the Arabs, although the Makaranga themselves are not a seaboard people, and that *Shava* is their word for 'to sell or barter', while to the Himyarites *Saba* meant 'to travel for a commerical purpose'. Not less suggestive is the study of place-names, and while I do not suggest that I have evidence on which any conclusion can be based, I do contend that these investigations may prove to be of a most fruitful character. It would be interesting indeed to see what evidence linguistics can bring in respect of the relationship of South Africa with Madagascar, and also with Polynesia through Madagascar, where the tribe once dominant politically, the copper-coloured Hova, are ethnologically and linguistically Melanesians amid the darker-hued Sakalavas and other negroid tribes. It may even be that such studies will conjure up to our minds pictures of great migratory movements with Arab dhows and South Sea proas cleaving the waters of the Indian Ocean. Only last year a canoe constructed of wood native to south-eastern Asia was found in Algoa Bay.

Finally, in this survey of what Africa can give to science I would refer, with the utmost brevity perforce, to Africa as a field, favoured as is no other, for the study of all those complicated problems which arise from the contact of races of different colours and at diverse stages of civilisation. Of those problems, ranging from the investigations of the biological factors involved in the conception of race to the practical problems of the administration of backward peoples, I need not speak. They have come to be part almost of the everyday thinking of most civilised men. What I would emphasise is that in Africa, as nowhere

else, the factors which constitute these problems can be studied both in isolation and in varying degrees of complexity of inter-relationship, that in Africa we have a great laboratory in which to-day there are going on before our eyes experiments which put to the test diverse social and political theories as to the relations between white and coloured races, that in Africa there are racial problems which demand solution, and the solution of which will affect or determine the handling of similar problems throughout the world. We hear men speak of the clash of colour, and are sometimes told that Africa is the strategic point in that struggle. I think of it rather as the continent which offers the richest opportunities to those who would investigate racial problems in the true spirit of science, and so discover the solutions, which may yet enable that clash to be averted and the threat which it implies to our civilisation to be dispelled.

Science and the Future of Africa.

I have sought—briefly and all too inadequately—to indicate some of the lines along which Africa seems to be able to make a distinctive contribution to science. It remains for me, yet more briefly, to speak of Africa's challenge to science, and to seek to answer the question, What can science give to Africa? I shall not stop to emphasise the point, that the greatness of Africa's potential contributions to science, the key which perhaps she holds to the riddle of human origins, the intriguing vistas opened up in the study of her relationship with South America and Australasia with its suggestion of past continental continuity, that all these and more constitute a challenge to science to actualise those potentialities. Let me seek rather to define the twofold challenge of Africa in another way. First, Africa defies science to unravel her past. Throughout history she has ever been the continent of mystery. She was so to that pioneer of geographers, Herodotus, to whom nothing that was told him about Africa was so improbable that he declined to give it credence. She was so to the Romans, who regarded Africa as the natural home and source of what was strange and novel and unaccustomed. She was so to the navigators who did so much to break down the barrier wall between the Middle Ages and the modern world; and though in our day the geographical mysteries of Africa have in large measure been solved, the work of the prober of her scientific secrets is only beginning.

Then, secondly, Africa challenges science to define, to determine, and to guide her future. If the great resources of this vast undeveloped continent are to be made available for humanity in our own and the succeeding generations, science must make it possible for the man of European race to undertake the work of development, by showing him how to protect himself, his stock, and his crops against disease, by enabling him to conserve and utilise to the greatest extent the soils, the vegetation, and the water supplies of the continent, by bringing to bear the resources of modern engineering on the exploitation of its wealth, and not least by determining the lines along which white and coloured races can best live together in harmony and to their common advantage.

That is the challenge of Africa to civilisation and to science. It is not now thrown out for the first time; it is not the first time that it will have been taken up. It is in Africa that the Greco-Roman civilisation won some of its most glorious triumphs, in Africa that the spade of the archæologist has in our day, by uncovering great Roman towns with noble public buildings and efficient irrigation systems, provided impressive evidence of the magnitude of the achievement of Roman Imperialism. But Rome failed to conquer Africa for civilisation, and left the challenge to those who were to follow after. She failed chiefly for two reasons: the might of African barbarism and the defiant resistance of African Nature. We in our day, confronted by the same challenge, still have the same enemies, hitherto victorious, to contend against. But we meet them with the advantage of having resources at our disposal which our Roman predecessors lacked. It is to use those resources effectively that Africa challenges science.

In dealing with African barbarism we have weapons such as Rome could never dream of, and not the least valuable are those provided by the scientific investigation of the native peoples of Africa. The way to the solution of the problems presented by African barbarism is to be sought in an understanding of the character and mentality of primitive peoples, in the exploration of those regions in their social life where are to be found the factors that determine their reaction to diverse methods of administration. The study of African languages and of African anthropology is therefore fundamental to the development of the continent. For that work Africa possesses special advantages, and one can but hope that the facilities now being built up in our South African universities will be recognised in Britain and elsewhere, and become an important factor in the response of science to the challenge of Africa.

Not less formidable is the conquest of African

Nature, for the achievement of which also we in our day are far better placed than were the Romans. It is modern science which gives us that advantage. Three great tasks confront science in the conquest of African Nature. First, science must make Africa safe for the white man to live in. I have spoken of the opportunities which Africa offers for the study of tropical diseases as likely to yield results of significance for science in general. But primarily, will those results be of significance for the development of Africa? This part of the challenge of Africa is not lightly to be taken up. Africa has taken heavy toll of science. The recent deaths in Nigeria of Stokes, Young, and Noguchi, worthy followers in the tradition of Lazear and Myers, are a reaffirmation of the gravity and insistence of that challenge. The importance for the cause of civilisation of a successful response to that challenge cannot be better illustrated than by the story of the construction of the Panama Canal. De Lesseps attempted the task and failed. For every cubic yard of earth excavated by him a human life was sacrificed to yellow fever or malaria. It was the successful attack some twenty years later, under the direction of General Gorgas, on the death-dealing mosquito, that made possible the completion of one of the most important engineering enterprises of modern times.

Secondly, science must combat the foes which have to be contended with in the development of African agriculture. Africa is prodigal indeed in the production of insect and other foes to cattle and to crops. Science is already making an effective response to this part of the challenge. But there is much that remains to be done, and we shall be none the worse for the timely realisation by the politician and the administrator of the contributions which science can make. All too often in the past, settlement schemes have been undertaken and ended in disaster in areas unhealthy to man, beast, or crops, when, if the scientist had first been called in, precautions might have been taken which would have averted the calamity.

Finally, science must harness the great resources of Africa. Here there are suggested to us all the varied contributions which the engineer can make in the work of development. Has not the Institution of Civil Engineers defined the ideal underlying all engineering activity as "the art of directing the great sources of power in Nature for the use and convenience of man"? Africa offers abundance of opportunities for the realisation of that ideal. It is not by working in isolation that the engineer will realise it, but rather by co-operation with his colleagues in other branches of science, and by the correlation and co-ordination of the essential data which they must do so much to provide. First in the order of engineering development come the civil and mining engineers. Their tasks are the provision of facilities for communication, for health, for the conservation of agricultural assets, for the production of raw material, and for the development of mineral resources. In their train there follow, with the advent of industrial activity, the mechanical and electrical engineers. Their tasks are to make the fullest use of the revolution in ideas of transport, including transport by air, which have resulted from the perfecting of the internal combusion engine, and to secure the maximum advantage possible from cheap production and efficient distribution of electrical power. The day must come, to give a concrete instance, when the Victoria Falls, with their immense water resources, will mean much more for Africa than Niagara to-day means for America. Later still there will be called in the services of the chemical engineer, ever engaged in problems of research to ascertain the most advantageous processes of converting raw materials into manufactured articles. In all these tasks it is the South African engineer who has, under the conditions of an undeveloped land, built up a technique and practice suitable to African requirements and showing promise of wider applicability, that we may well expect to assume a position of leadership and of inspiration. These are some of the ways in which science can respond to the challenge of Africa.

The picture which I set out to portray I have now completed. I have tried to suggest something of the magnitude of the rewards which Africa has in store for the scientist who has the enterprise to adventure and the vision to see. I have sought also to be the medium of the challenge presented to science by Africa's opportunities and needs. It is a vast canvas on which I have had to work. On it I have drawn but a few sketchy outlines. Yet I hope that the vision stands out clear. I hope that I have said enough to convey the power of its inspiration. Not least do I hope that our visitors will play a great part, in the time that they will spend with us, in filling in some of the details of the picture, and in quickening and vitalising its message for the scientists of South Africa. It is to them chiefly that it makes its appeal. The development of science in Africa, of Africa by science—that is the promised land that beckons them. I believe that they will not be disobedient to the vision.

Summaries of Addresses of Presidents of Sections.[1]

Cosmical Physics.

Lord Rayleigh's presidential address to Section A (Mathematical and Physical Sciences) is entitled "Some Problems of Cosmical Physics, Solved and Unsolved". He begins by reviewing the more outstanding cases of celestial spectra which still resisted identification after the discovery of helium. He traces how the strong lines of the nebular spectrum, formerly attributed to 'nebulium', were identified by Bowen as due to doubly ionised oxygen. He then goes on to the auroral spectrum, and after describing McLennan's investigations, which have led to the identification of the prominent green line as belonging to the arc spectrum of oxygen, he discusses the problems involved in the red line of the aurora, which up to the present has not been definitely traced to its origin. A nitrogen origin appears the most probable.

The spectrum of the solar corona is also regarded as an unsolved problem. Lord Rayleigh rejects the solution proposed by Freeman, who attributes the lines to argon. It is of interest that Russell and Bowen, in a paper which has appeared in the *Astrophysical Journal* since the address was prepared, have taken the same view.

Lord Rayleigh then discusses the conditions of excitation of some of these spectra. The theory of solar corpuscular streams is briefly reviewed, and some of the difficulties which have made it necessary to modify the original form of the theory as proposed by Birkeland. Reference is made to recent observation on echoes of short wave wireless signals, which are heard after an interval of several seconds. These echoes appear chiefly during times of magnetic disturbance, and Störmer has attributed them to reflection from the corpuscular streams of solar origin which exist in the earth's neighbourhood at such times. A very recent discussion by P. O. Pedersen adopts the same view.

The nebular spectrum, it is considered, is probably excited by ultra-violet light of short wavelength. Stress is laid on the peculiar richness in ultra-violet light of the central stars of planetary nebulæ, as emphasised by W. H. Wright before the origin of the nebular spectrum was realised. The mysteries still involved in absorption by the dark nebulæ, and in the excitation of cometary spectra, are also considered.

The address then passes to the discussion of the metastable states of excitation of atoms involved in the various spectra which have been discussed. Many of the lines of the nebulæ and the green line of the aurora are of the kind forbidden by the selection rules of the quantum theory in its present imperfect form. Laboratory experiments on mercury vapour, which is more amenable than oxygen or nitrogen to this purpose, have shown the possibility of observing such lines either in emission or absorption, in regions undisturbed by extraneous electric or magnetic fields.

After discussion of a few points in connexion with the layer of atmospheric ozone overhead, the remainder of the address is devoted to considering the cosmical possibility of unknown elements of higher atomic number than uranium, the highest known terrestrially. The list of elements is practically complete up to uranium, at which point it abruptly stops. It would seem, therefore, that any process of gravitational separation which has left heavier elements in the sun's interior, while eliminating them from the earth, must have succeeded in making an extraordinary clean and sharp cut. On the other hand, it appears that uranium must be coming into existence on the sun, as its duration is small compared with the probable age of that body. The analogy of radium would lead one to assume that uranium has a parent body of higher atomic weight. But such a parent body, if it exists, is *ex hypothesi* analogous to known radioactive bodies; thus even if we postulate it, we do not get any direct support for the view that matter may exist which is capable of dissolving entirely into radiation.

The Relation of Organic Chemistry to Biology.

In his presidential address to Section B (Chemistry) Prof. G. Barger traces various trends in the development of organic chemistry, particularly in relation to biochemistry and physiology. After directing attention to the isolation by Scheele of various organic acids and his synthesis of potassium cyanide, the address contrasts the early preparative investigation of natural products by some of the older chemists, such as Fourcroy and Vauquelin, with the work of others who were primarily inter-

[1] The collected presidential addresses delivered at the meeting are published under the title "The Advancement of Science, 1929". The volume is obtainable at 6*s*. of all booksellers or from the British Association, Burlington House, London, W.1.

ested in theoretical questions of radicles, substitution and types. This latter work led ultimately to the theory of structure, which soon became ground common to all.

A knowledge of structure gave a great impetus to synthesis, on which important industries were based. The number of known carbon compounds increased very rapidly and is now little short of a quarter of a million, but only a small proportion of these occur in Nature and a very small proportion are of general biological interest. The first systematic investigation of a whole group of biologically important substances was that of the fats by Chevreul; similarly comprehensive investigations of metabolic products were made later in Germany by Baeyer, Fischer, Willstätter, Wieland, and Windaus, when they applied organic chemistry to the study of the purines, sugars, proteins, plant pigments, bile acids, and sterols. A statistical analysis of papers on organic chemistry published during the last year in the *Berichte* and the *Journal of the Chemical Society* leads to the conclusion that British organic chemists are more interested in theoretical questions than their German colleagues and give much less attention to natural products.

The new borderline subject of biochemistry, based largely on the work of van 't Hoff and of Emil Fischer, may be said to have been definitely marked out early in the present century; thus in 1906 journals devoted to biochemistry were founded in three separate countries. The biochemist is not only concerned with the properties *in vitro* and the isolation of biologically important substances; he also studies the transformations which these substances undergo *in vivo*, when acted on by enzymes. These two sides of the subject have been called the descriptive and the dynamical. Both utilise to the full the resources of organic chemistry, its theoretical conclusions as well as its technique. In addition, the biochemist gives much attention to the working out of special methods of preparation and of analysis, required for the study of the complex problems with which he is concerned. These various aspects and relations of biochemistry are illustrated in the address by reference to recent investigations.

The taxonomic value of organic chemistry is very slight, except in the classification of bacteria, fungi, and lichens. Among Phanerogams the chief example of its utilisation is probably the genus *Eucalyptus*. The organic chemist may turn natural relationship to account in his study of alkaloids, but the systematic botanist is not influenced by their presence or absence.

Prof. Barger ends by pleading for a sympathetic teaching of organic chemistry, adapted to the needs of biological and medical students, and in this connexion quotes with approval from the presidential address to Section I by Prof. Lovatt Evans at Glasgow in 1928.

National Surveys.

The subject of Brigadier E. M. Jack's address to Section E (Geography) is national surveys. The duties and functions for which, in the opinion of the president, a national survey should be responsible, are discussed; then the work of the various national surveys, both foreign and in the Empire; and conclusions are drawn, with particular application to South Africa.

The main object of a survey is held to be the production of a map. The various operations necessary for this object are enumerated, and it is argued that a properly organised survey should be responsible for all these operations, from the initial triangulation to the printing, publication, and sale of the map, and its subsequent revision.

The question of maps is considered under the two main headings of cadastral and topographical. The characteristics of these two kinds of maps are described, and the opinion expressed that a national survey to be complete should be responsible for the production of both kinds.

Proceeding to a consideration of the surveys of the world, it is shown that the surveys of Europe have similar characteristics. They are mostly military in character, and their responsibility is confined to the production of topographical maps. Cadastral maps are produced by an independent department (usually financial) and are rarely published. Egypt forms a striking contrast, its survey (due to British organisation) conforming closely to the standard laid down.

In the United States various independent departments are responsible for different branches of survey. There has in the past been much independent action and doubtless some friction; but co-ordination has now been secured by the establishment of a Federal Board of Surveys. Very much the same description applies to the surveys of Canada.

The Survey of India produces only topographical maps. In Australia and New Zealand, on the other hand, topographical mapping is much neglected. Information is given as to various surveys in the African Colonies and Protectorates. A short description is then given of the Ordnance Survey of Great Britain.

The question of countries which have a divided

control of their surveys or have neglected some part is considered, and it is shown that such countries have suffered in consequence.

The position in South Africa is then considered. The recent Survey Act of 1927 has put survey in the Union in a much sounder position than it has ever been before. While responsibility remains divided between the Surveyors-General of the four Provinces and the Director of the Trigonometrical Survey, a 'Survey Board' has been established, consisting of these five officials. While this does not go so far as the Survey Commission of 1921 recommended, it is a great step forward in securing unity of control and uniformity of practice.

After touching on the difficult question of cadastral mapping in the Union, the question of a good topographical map of the country is discussed. Examples are given, taken from South Africa itself and from other countries, of the great need for such a map, and of the waste of time and money which results from the lack of it.

In conclusion, it is pointed out that South Africa has a great survey tradition, some of the finest survey work in the world having been done in the country. South Africans are urged not to lag behind, but to set an example to others; and to be determined to have a national survey adequate to their place among the nations, and worthy of their history and great traditions.

Physiology in the Treatment of Disease.

Prof. W. E. Dixon's presidential address to Section I (Physiology) reviews briefly the history of treatment in disease from the middle of the last century, when S. Skoda and K. Rokitansky (in Austria) perfected a system of physical diagnosis which has had a practical bearing on medicine ever since. Skoda made many experiments with drugs on the patient without any expectation of producing benefit; the patients were not improved, and Skoda thought it mattered little how the patient was treated. These views held the field even to the beginning of the present century, especially in Great Britain.

The experiments of Joig and his pupils in 1825 with camphor, digitalis, and other drugs on healthy men added nothing of value to our knowledge. Subjective sensations are produced, which are erroneously attributed to the drug which has been taken. Some experiments made with the late Dr. Rivers to illustrate these imaginary sensations were described. Such experiments on men as were made by S. Hahnemann and his pupils, by Perkin with his retractors, and by more modern physicians with their mystic apparatus, are valueless without proper controls. The influence of science on treatment is illustrated by reference to chemo-therapy and the internal secretions.

At one time hopes ran high that the chemical structure of the molecule might indicate pharmacological action. During the last fifty years, many laborious researches have been conducted with this object; to modify the molecule that it may conform to some required action. But the mystery remains as mighty as ever. It is most probable that subtle energy factors binding the molecule—factors not displayed in a formula—control the action; certain it is that drug action is not determined directly by chemical combination with body constituents, but rather by delicate physical processes such as those of absorption, solution, and surface tension. Illustrations are provided by action of the organic compounds, of the metals, dye-stuffs, and certain alkaloids.

In the last twenty years, much evidence has accumulated to show that the glands of internal secretion are responsible for the regulation of growth, of metabolism, and often for our appearance if not for our very character. Exaggeration or diminution in the secretion of one or other of the tissues may induce conditions so decided as to be obvious to everybody, though the effects produced by minor alterations in the co-ordination of the several secretions may not be so evident. Giants and dwarfs, unusual pigmentation and anæmia, disproportion in the growth of the skeleton, such as enlarged hands and face, bulging deer-like eyes or oriental eyes and beards in women, are noticeable to everyone; excessive fatness or emaciation, a choleric or bucolic temperament, cause no comment, yet may equally arise in the victim from a want of co-ordination in the internal secretion.

The general outlook and significance of drug therapy was led into new channels when it was revealed that the animal body through these glands elaborates its own drugs, stores them generally at the seat of formation, and doles them out to the tissues to meet the needs of the economy. Some of these drugs are of the nature of alkaloids comparable with those elaborated by plants. It is a remarkable fact that when Nature elaborates a drug in either a plant or an animal, that drug is invariably the ideal drug for producing the action for which it is characteristic. No drug relieves pain like morphine or produces local anæsthesia so well as cocaine; no drug paralyses the parasympathetics so perfectly as atropine or the motor nerves so effectively as curarine; strychnine super-

sedes all other drugs in exaggerating spinal reflexes, and caffeine in its remarkable power of stimulating the psychical centres of the brain. Of the animal drugs, adrenaline has a superlative effect on the sympathetic system, pituitary on the uterus, and thyroxin on general metabolism.

The elaboration of the drugs in Nature is on biological lines and the key always fits the lock: it seems as if Nature always says the last word on the particular type of drug she elaborates. Certainly organic chemists have up to now done little to improve on her products.

In conclusion, Prof. Dixon remarks that science is now engaged in endeavouring to remedy the evil effects which she has produced, to which he attributes tuberculosis, rickets, and especially the neurotic tendency in the highly civilised nations.

Experimental Method in Psychology.

The topic dealt with by Mr. F. C. Bartlett in his presidential address to Section J (Psychology) is the value and difficulties of experimental method in psychology. The earliest experimentalists in psychology were physicists and physiologists, most of them with a pronounced philosophical bias. They developed methods and set up standards which in various ways have hindered the growth of psychology as a true biological science. The physicist, approaching any problem of human reaction, tends to lay the chief burden of explanation upon the stimulus, by the simplification, control, and variation of which he explains observable differences in response. The stimulus is treated as outside the response itself. The difficulties to which this may lead are illustrated by special reference to the psycho-physical methods developed by Fechner, G. E. Müller, and others, and particularly by a consideration of how 'doubtful' judgments have been dealt with in psycho-physical series.

The physiologist, approaching similar problems, tends to lay chief stress upon the response side of the stimulus reaction situation. He legitimately isolates this so far as possible, often cutting it out of its wider organic setting, and shrinking from speculation about central processes until he has learned as much as possible about peripheral processes and their mode of operation. The experimental psychologist has often tried to borrow the physiologist's terminology, but since he has to try to deal with the intact organism, the wide variability of response when it occurs in its normal setting constantly forces him back upon central processes, and he may tend to lose himself in sheer speculative physiology of the central nervous system. This is illustrated by a reference to experimental work upon the special senses.

In dealing with so-called 'higher mental processes', the experimental psychologist has again far too often attempted to imitate the methods of older established sciences. Extreme simplification of stimuli has regularly been confused with isolation of response, with disastrous results. This is illustrated by a study of the classical experiments of Ebbinghaus on memory, and by a consideration of experimental work on recognition.

Not only has the experimental psychologist been too submissive to physical and physiological methods, but also he has often been misled by the pursuit of philosophical ideals. The results of experimentation upon some special field of human reaction have frequently been elaborated into very wide systems of explanation which claim a finality that they certainly do not possess. This is considered in reference to contemporary movements, and particularly to the work of the *Gestalt* psychologists, of Prof. E. R. Jaensch, of Prof. C. E. Spearman, and of the behaviourists.

In psychology, the experimentalist is attempting to find out the conditions of the various responses or modes of conduct that make up the lives of animals and human beings. He is primarily interested in the intact organism and the intact mental life. He may gain help from a study of instances in which certain types of response have been lost, leaving still a very complex organism, or mental life, to effect a readjustment of what remains. This is clearly a very different matter from cutting out the partial response and studying that by itself. The perfecting of objective control, in a psychological experiment, does not reduce the observer to a single sense, or a single cognitive or emotional process, but, leaving him as complex a reactive agent as ever, forces him to make up on the spot a type of total reaction fitted to this special experimental environment.

The main conclusions drawn are: (1) The experimentalist in psychology is at present, and perhaps always will be, as much clinician as experimenter. He must bear in mind that the conditions of all reactions studied from his special point of view branch very widely, and that to him the study of indirect cues leading to any response may be of primary importance. (2) No experimentalist in psychology must profess, with unvarying belief, the dogma of constancy of objective conditions. Many of the most important characters that dominantly set the course of human reactions belong directly to the organism with

which the experimentalist is dealing, to its immediate and remote past history, and to its present specific and general state of adaptation. These characters may be more diversified by rigidity than by variation of outward circumstances. (3) Since the psychologist is dealing with biological phenomena, he must be satisfied by stating trends, directions, proclivities, rather than dogmatic laws. (4) There is need for much more critical care than has usually been exercised before the results of specialised investigations are erected into comprehensive 'explanatory' systems.

If these conclusions are held firmly in mind, experimental psychology will yet prove equal to its task of building up a sound scientific study of complex response in animal and man.

Modern Movements in Education.

In his presidential address to Section L (Educational Science), Dr. C. W. Kimmins deals with changes in the field of education since the meeting of the British Association in South Africa in 1905. The most important development during this period has been the concentration of interest on a hitherto comparatively neglected field of investigation—the mental welfare of the pre-school child. In this connexion a brief account is given of the valuable researches on animals of Köhler and Yerkes, which throw much light on the early stages of the learning process in the child. The necessity of making the young child the object of a long series of conditioned experiments—even if this were possible—is thus obviated.

Reference is made to the great difficulty of bridging the gulf which separates the child's world from the adult world, and of thus acquiring a fairly adequate conception of the real meaning of the child's language in adult terms. The value of the work of Prof. Jean Piaget and his colleagues in helping to solve this problem is fully recognised by all students of child-psychology.

When the age is reached for compulsory school attendance, and there becomes available a large mass of valuable material for observation and experiment, the task of the investigator is rendered a comparatively easy one. In the pre-school period, however, the absence of such material under suitable conditions is a serious matter. The Fisher Act of 1918, with the prospect of the establishment of a large number of nursery schools, gave promise of removing this disability, but, unfortunately, financial difficulties prevented the full realisation of this desirable project.

Quite apart from the value of the nursery school for purposes of child study, there are many obvious reasons for pressing forward the demand for the recognition of this type of institution as a natural element in any progressive scheme of educational organisation. The nursery school links up the home with the school to the great advantage of both. Properly constituted, moreover, it may to a large extent prevent many of the maladjustments with which the school clinics and child guidance clinics have to deal. Prevention by natural means is infinitely better and far less expensive than curative processes.

The value of vocational guidance by means of appropriate psychological tests, in giving increased facilities for the more successful marketing of the produce of our schools in the future, is dealt with in some detail. The experiments carried on under the direction of the National Institute of Industrial Psychology have been crowned with considerable success. In days to come, boys and girls on leaving school will be in possession of information, based on scientific principles, which will indicate the type of employment in which they can engage with the greatest satisfaction to themselves and to their employers.

The pamphlet of the Board of Education entitled "The New Prospect in Education" is far and away the most important document which has been issued by the Board in recent years. The reorganisation of educational procedure envisaged marks a great advance. This valuable reform occupies in many ways a very prominent and honoured position among modern movements in education.

Printed in Great Britain by R. & R. Clark, Limited, *Edinburgh.*

America may be held to militate against its American origin and rather support the view that it was an introduced plant. Further evidence in support of the eastern origin of the coconut and also of its power to spread independently is afforded by the fact that several islands all grouped together bear the name Cocos Island or have a 'Cocos Bay'. These islands were apparently uninhabited at the time of their discovery and received their names no doubt owing to the fringes of coconut palms on their shores, as it was the tendency of the Portuguese and Dutch in the sixteenth and seventeenth centuries to name uninhabited islands by some distinguishing feature they presented.

Another fact which lends some support to the views of De Candolle, Beccari, Chiovenda, E. D. Merrill,[11] and others, that *Cocos nucifera* is of eastern rather than American origin, is afforded by the recent discovery of fossil nuts of a *Cocos* in the Pliocene deposits at Mangonui, North Auckland, New Zealand. These have been named *Cocos zeylandica* by Edward W. Berry,[12] and, though they are quite small, they show no marked features, except as regards size, to differentiate them from the existing genus *Cocos*.

O. F. Cook has taken infinite pains to try to prove that the Coconut palm originated in South America, but many of his arguments may equally well be used in support of its Polynesian origin. With regard to the antiquity of the palm in America, he lays some stress on the finding of a carved coconut shell in a grave in the Chiriqui district on the Pacific coast of Panama. This bowl is figured in Cook's "History of the Coconut Palm in America",[13] but it is not stated whether the grave was a prehistoric one or not. I am informed by the authorities at the British Museum that the design on the carved shell is certainly not aboriginal American, nor does it resemble anything from the East Indies at all closely. It is considered far more likely to be "a post-Spanish American product influenced by European designs such as were used by Indians in many parts of America after the arrival of the white man".

The highly polished coconut cups of Spanish South America are mentioned as a suggestive analogy, and also the similar floral patterns of modern Indian painted pottery, etc.; it is not thought that the carved shell carries any weight as evidence either for or against the American origin of the coconut palm.

The fact of the finding of some particular bowl in a country needs some further support in the way of evidence, to prove that it may be a product of the country where it has been found, since a good deal of false deduction might be based on the finding of shells of the double coconut (*Lodoicea*), in India, where they are used as drinking bowls and for other purposes.[14] Cook also attaches importance to the occurrence of coconut palms on Cocos Island, situated in the Pacific Ocean some 300 miles to the west of Panama, which since the coming of the Spaniards has not been inhabited and the coconut palms have almost disappeared. After considering the various suggestions made by Cook, there seems to be nothing against the view, held by De Candolle, that the coconut palms on this island might have been brought there by early Polynesian voyagers. From this island, or more possibly by the landing of some of these early voyagers on the Pacific coast of Central America, they became established on the mainland and were in the course of time carried far and wide.

Mr. H. C. Sampson, who carefully studied Cook's work, has kindly supplied me with the following notes:

The three main points raised by Cook are:

1. That the coconut must have plenty of soda salts for it to thrive. Therefore it must be a native of those parts of America where such alkali abounds in the soil.
2. That the coconut will not establish itself on a coast-line without the aid of man.
3. That the fibrous covering on the coconut is intended to hold a supply of moisture for the roots of the young seedling and not to act as a float.

As to 1. Coconut palms are able to stand a high percentage of soda salts in a soil provided there is very free drainage and aeration. Where these are absent the tree immediately becomes unhealthy. Tidal action on a sandy sea coast supplies the necessary drainage and aeration, hence trees on a sandy sea coast are usually healthy, while those facing a lagoon or backwater are unhealthy. Health, according to Cook, is the ability to form fruit; but this is not so. Healthy trees need never bear fruit. They will, however, bear fruit if the necessary plant food is made available to them in the soil. Coconuts will grow quite well in soils deficient in soda salts. This has been proved by the Bombay Department of Agriculture, when the Government of that Presidency was considering the question of remitting the duty on salt required for the purpose of manuring coconut trees in the Konkan and in North Canara.

I myself have seen coconuts doing very badly on soils which were inclined to be alkaline, though the trees were afterwards made to bear heavily by breaking up the alkaline pan, which one usually sees associated with such soils.

With regard to 2. I have seen self-sown coconuts establishing themselves on the cays off Belize which are being formed in the shallow water. The young palms are able to compete for light with the young mangrove which under such conditions is inclined to remain stunted. The coconut groves on the east coast of Trinidad in the region of the Cocal are undoubtedly self-sown. These are said to have originated from the wreck of a French schooner laden with coconuts. One sees the trees growing in clumps often four or five together or in close proximity, which would not be the case had they been planted by man. That coconuts do not do this more frequently is due to two causes: First, that though the seed may germinate it cannot survive where the shore vegetation is liable to overshadow the seedlings, and secondly, in the open

[11] Merrill, E. D. "Enumeration of Philippine Plants", Bureau of Science, Manila, vol. 4, pp. 70-71 (1926), also "Notes on the Flora of Manila with special reference to the introduced element", *Philippine Jour. Science*, vol. 7, pp. 168-192, 197, etc. (1912). Dr. Merrill informs me he has now altered the views expressed in his footnote on p. 192, and does not agree with Cook as to the American origin of the coconut.

[12] Berry, E. W. *American Jour. Science*, **12**, No. 69 (September 1926). Specimens of these nuts were kindly sent to Kew in March 1927, by the curator of the Auckland Museum and are now exhibited in Museum No. 2.

glare of an exposed beach it is not possible for the husk to retain sufficient moisture to enable the young roots of the coconut to feed on the husk.

With regard to 3. It is very difficult to get coconuts to germinate in a dry climate without initial shade and constant watering. The fruit when it is ripe gives up its moisture from the husk, and it can only get this again by coming into direct contact with moisture either from the soil or from continual rain. Thus on the sandy coast soils of Ceylon and southern India, seed coconuts have to be nearly buried in the sandy soil, which has to be kept continually moistened, and even under such conditions germination is much slower than it is in countries with a more evenly distributed and heavier rainfall.

It is clear that natural regeneration would be impossible for the coconut in a dry country such as Cook claims to be the natural home of the coconut. It seems to me much more likely that the coconut was taken to America by immigrants arriving there prior to the discovery of that continent by western civilisation than the reverse.

Turning now to the mode of dispersal of the coconut:

The sight of the Cocos-Keeling Islands, or Atolls, in mid-ocean on the direct route from Ceylon to Western Australia, and some 700 miles to the south-west of Java and the Straits of Sunda, led me to look into the early history of these Islands and search for records of the occurrence of coconuts on other uninhabited islands in the Pacific Ocean.

Coconut palms were well established on these uninhabited Islands when Captain Le Cour visited them in 1825,[15] before Captain Ross arrived there that same year, for he "carved his name on the Palm trunks". H. B. Guppy brings together some very interesting evidence in connexion with the coconuts growing on the Cocos-Keeling Islands.[16] In a general map of the Eastern Archipelago, published in Amsterdam in 1659, they are named the Cocos Islands, showing that the coconut palm was then a feature of the group. Again, in Jan de Marre's plan of the islands in 1729, coconut palms are figured with the simple, yet probably unintentionally true, remark: "it would seem that Nature herself has produced these trees", and in 1753 Van Keulen described them as being wooded.[17] Further, some fifteen or sixteen years before the islands were occupied (see Horsborough's "India Directory", 1809), it is stated that they were "covered with trees, principally the Cocoa-tree" (=coconut palm).

Charles Darwin visited the Cocos-Keeling Islands[18] in the year 1836, some ten years after their rediscovery, and found them thickly covered with full-grown coconut palms. He points out that at one time they must have existed as mere water-washed reefs, and therefore "all their terrestrial productions must have been transported by the waves of the sea". It is also of interest that Darwin refers to the occurrence of *Birgus latro* on these islands, and this suggests that both coconut and crab were brought to the islands by the same means.

From this evidence it appears certain that the coconut palms on the Cocos-Keeling Islands were established there when they were uninhabited, and there is also strong probability that they were the result of ocean-borne nuts which had drifted there, with many other seeds from the east, as Guppy points out. From information kindly supplied by the Hydrographer to the Royal Navy, I find that the general trend of the ocean currents in this region is from the east, westwards, so that any flotsam and jetsam reaching the islands would tend to come from Java or Sumatra or from the Sunda Straits.[19] It seems not unreasonable to assume that the original nuts which have given rise to the coconut groves on the Cocos-Keeling Islands reached there as ocean-borne nuts from the islands to the east, and this supposition may be held to give some additional support to the view that the islands of

FIG. 1.—Young coconut among *Ischæmum muticum*; background, *Desmodium umtellatum*. Krakatau.

the Eastern Archipelago of the Pacific Ocean should be regarded as the original home of *Cocos nucifera*.

It is, of course, true that young sprouting coconuts on the strand are constantly destroyed by the land crabs, but it seems not unreasonable to assume that a few nuts, out of the many which must have been washed ashore, would have been covered by drift sand and so protected from the land crabs, and that from those which successfully germinated the dense groves of coconut palms on these and on other uninhabited islands had their origin.

Wood-Jones mentions that water-borne coconuts can be seen germinating all round the lagoon shores of Cocos Island, and adds there is "no reason to suppose that any human agency was involved in the first planting of the coconuts in Cocos-Keeling".

The coconut palms now growing in the Bay of Cocal, Trinidad, are reputed to have resulted from nuts washed ashore from a ship wrecked on the coast, and also, as mentioned earlier, on some of the cays which are being formed off the coast of British Honduras self-sown coconuts may be seen.

[18] Darwin, Charles. "Voyage of the *Beagle*", chap. xx.
[19] Darwin, in the "Voyage of the *Beagle*", quotes Holman's "Travels", vol. 4, p. 378, where an account is given, on the authority of Mr. Keating, of seeds, etc., from Sumatra and Java, washed up on the Cocos-Keeling Islands. Among them were "the cocoa-nut of Balci, known by its shape and size".

Coconut palms are also found on small rocky islets off some of the Fiji Islands, where evidently the nuts have been cast up by the sea and could never have been planted.

Guppy, in his paper on the Cocos-Keeling Islands (*loc. cit.*), produces weighty evidence to show that the coconuts there must have been water-borne and have germinated when washed up on the strand. He also brings evidence in support of the contention that the coconut is able to germinate without human intervention when washed up on Fijian beaches, whether brought down by a river or transported by an ocean current.[20]

Leguat, in his account of the Island of Rodriquez (1691),[21] says: "The sea having thrown us up some Cocos which began to bud, we planted some of the fruit some months after our arrival, and when we left the place the trees were four feet high." These nuts he believed came from the Island of Ste. Brande. There are also two islands called Coco and Cocos in this region.

A definite proof that the coconut will germinate unaided when washed ashore has been afforded in the case of the Island of Verlaten, which lies to the north-west of the Island of Krakatau in the Straits of Sunda, between Java and Sumatra. Verlaten Island, which is uninhabited and uninhabitable, was visited in April 1919 by Dr. W. Docters van Leeuwen, now Director of the Botanic Gardens, Buitenzorg, and he records,[22] with a photograph, the finding there of a coconut palm sprouting in the drift mud—an accretion of soil containing pumice stone—at only a few yards distance from the sea. This proves conclusively that an ocean-borne coconut can germinate without human aid, as Beccari asserted, and refutes the opinion of Hugo de Vries, O. F. Cook, and others.

When I was in Java in March 1928, Dr. Docters van Leeuwen very kindly gave me prints of two photographs of two young coconut palms, similar to the one on Verlaten, which he found growing on the beach of the Island of Krakatau (Fig. 1), which since the great eruption of 1883 has remained uninhabited. In one case the young palm is partly overgrown by *Ipomœa denticulata*; in the other, here reproduced, the palm is growing amongst the grass *Ischæmum muticum* and, despite the competition with other vegetation, they both appear to be holding their own quite successfully. These observations afford satisfactory evidence that ocean-borne nuts can germinate when washed ashore on an uninhabited island and become established without the intervention of human agency, and the evidence which has been brought forward may be considered to strengthen the view that the Polynesian or East Indian Islands are the original home of the coconut palm.

Obituary.

PROF. L. T. HOBHOUSE.

THE death of Prof. Leonard Trelawny Hobhouse on June 21, at the age of sixty-four years, at Alençon, Normandy, is a heavy loss to science and philosophy. Martin White professor of sociology in the University of London since 1907, he has done more than anyone else in England towards the development of sociology as a scientific discipline; he has made contributions of the highest value to comparative psychology and anthropology; and his work on logic and metaphysics must entitle him to rank among the most distinguished systematic philosophers of recent times.

Already as an undergraduate at Oxford, Hobhouse was led through his interest in social reform to a deeper study of the nature of society and its relation to the wider problems of metaphysics, and throughout his life his scientific and philosophical researches were closely and intimately interwoven with his work as a politician and practical reformer. His passion for humanity and justice gave him tremendous driving power, while his love of truth and rare intellectual candour and willingness to profit from criticism and experience led him to ever fresh fields of investigation and ever deeper analyses of the foundations of knowledge. He illustrates in his life-work his own view of reason as a continuous and comprehensive effort towards harmony in experience whether in the fields of practice or speculation, and those who saw him at work, whether as a teacher, journalist, or chairman of trade boards, will have recognised in his endeavours the very same spirit which in other fields was exhibited in his persistent attempts at wider and more inclusive syntheses of the results of empirical research and metaphysical speculation.

Hobhouse laid his foundations solidly in an early work on the "Theory of Knowledge" (1896), in which he developed what may be termed an organic view of rationality which was to be the basis of all his future work. This has affinities with idealistic metaphysics but is essentially realistic. Hobhouse, indeed, may be regarded as one of the founders of modern realism, but unlike some of its more recent upholders who tend to reduce the cognitive function to a vanishing point, he seeks to vindicate the reality of mind as well as of the external world, of the self as well as the not-self, the conception of the self being built up by the same logical processes as go to the making of any other valid conception.

From his epistemological investigations Hobhouse turned to empirical research. In his "Mind in Evolution" (1901) he traces the growth of mind in the various forms of organic life, from its earliest manifestations in the gropings of unconscious effort to the full clearness of conscious purpose. This work was based on extensive experimental investigations, now generally regarded as among the most important pioneer contributions to the science of

comparative psychology. Moral and social development were then studied in his "Morals in Evolution" (1906), in which he utilises on a magnificent scale the data of anthropology and history in the establishment of a social morphology indispensable to the evolutionary point of view in sociology.

Armed with the conclusions derived from these researches into empirical fact, Hobhouse returned to the metaphysical problem in his "Development and Purpose" (1913; revised and rewritten in 1927). He shows that development consists in the extension of harmony through a series of syntheses. Development proceeds by the liberation of elements originally in conflict, the building up of structures of varying degrees of plasticity and coherence. The power behind this liberation and these syntheses is mind, essentially a correlating activity, manifested in all orderly structure, but more clearly in living organisms, which are interpreted as a modification of mechanical structure by teleological factors, and eventually emerging in the form of conscious purpose in the human mind, as expressed in the advancing movement of civilisation. Mind is, on this view, not coextensive with reality, but is the principle of orderly growth within it. It is limited by the material it works upon, and its purposes themselves undergo development. His fundamental principle, which he entitles 'conditioned teleology', is examined both from the point of view of the logical requirements of systematic explanation and its value as an instrument in scientific investigation in the fields of biology and sociology.

In a further series of works collectively entitled the "Principles of Sociology" (1918–1924), Hobhouse sought once more to apply his basic conception of mind as a correlating agency to the problems of social life. In the first of these, "The Metaphysical Theory of the State" (1918), he gave what is now generally regarded as the most penetrating criticism of the Hegelian theory of the State and prepared the ground for a social philosophy which would do justice at once to individual development and the requirements of the common good. In the "Rational Good" (1921) he works out his ethical theory of the good as a harmony of mind with its objects, a consilience of all living experience in a comprehensive system of purposes. In the "Elements of Social Justice" (1922) he applies these ethical ideas to the problems of social organisation and proves their value by the light which he is able to make them throw upon the practical problems of economics and politics. Finally, in his "Social Development" (1924) he gives us a synthesis of his scientific and philosophic studies bearing on the human problem. He first studies development from the point of view of empirical science and seeks to correlate the several aspects of social change in the light of non-ethical criteria analogous to those that might be employed in the study of biology. He then turns to the ethical problem of valuation, and finally argues that social and ethical development have a common end, rooted in the fact that the good is to be found in organic harmony. Taken together, these works must assuredly come to be recognised as the most comprehensive and scientific attempt that has yet been made to trace out the working and possibilities of rational purpose in human evolution.

Prof. Hobhouse was profoundly interested in the bearings of recent developments in the physical sciences upon the nature and validity of knowledge, as will be evident to readers of the revised edition of "Development and Purpose". He intended to devote himself on retiring from the chair of sociology to work on these problems. His sudden death has deprived the world of the results of his ripe speculation in this field of thought, and this can only deepen our sense of the loss of a great thinker, distinguished alike by a rare nobility and beauty of character, and by magnificent intellectual grasp and power.

MORRIS GINSBERG.

WE regret to announce the following deaths:

Sir Baldwin Spencer, K.C.M.G., F.R.S., emeritus professor of biology in the University of Melbourne and author, with F. J. Gillen, of works on the Australian aborigines, aged sixty-nine years.

Dr. W. J. Viljoen, Superintendent-General of Education of the Cape Province and first vice-chancellor of the University of South Africa, aged fifty-nine years.

News and Views.

IN his presidential address to the British Medical Association, delivered at Manchester on July 23, Prof. A. H. Burgess reviewed some aspects of the influence of other sciences upon the practice of modern surgery. The era of 'modern' surgery was inaugurated by Lister, and the present use of aseptic methods is merely the natural advance from the antiseptic technique as originally practised: antiseptics are still used for cleansing the skin and when sepsis is already present. As a sequel to the safety engendered by the use of these methods, the surgeon has access to all parts of the body, the spinal canal and thoracic cavity as well as the abdomen. Perhaps surgery is most indebted to the two sciences of physics and physiology during more recent years: it is only necessary to mention the aid brought by radiology, and radium and light therapy, by localisation of function in the brain, by the use of blood transfusion, by the discovery of vitamin D and insulin, and by the development of biochemical methods of investigating the body's functions. Prof. Burgess recalled in some detail the influence which these various discoveries had exerted upon surgical treatment. X-rays were first used in the accurate diagnosis of injuries to the bones and in diseases of the chest, the bones being relatively opaque and the lungs transparent: where the density of neighbouring tissues is similar, it is now the practice to administer or inject either a substance which is opaque to the rays, or air, which is transparent, and so by displacing tissues or tissue fluids enables a differentiation of the organ under examination to be made from the

neighbouring tissues. In Manchester, 20 per cent of patients pass through the X-ray department as compared with 1 per cent twenty years ago.

THE use of radium in treatment has had a twofold influence on the surgeon: it has sometimes replaced treatment by the knife, but at others a surgical approach to the seat of disease is necessary before the radium can be usefully applied. At the present moment, opinion seems to favour reversion to the external application of radium, but using relatively enormous quantities and at a much greater distance from the skin. The practice of actinotherapy has revolutionised the treatment of surgical tuberculosis, in which disease surgical removal of damaged tissues has been replaced by immobilisation and drainage, whilst the general resistance of the body is increased by its exposure to the sun or other source of light. The story of the development of our knowledge of the localisation of function in the brain illustrates the mutual reactions of clinical medicine and experimental physiology upon one another. The first step was clinical, the localisation of the speech area by Broca and the motor area by Jackson, and was followed by the experimental investigations of Ferrier, Horsley, Sherrington, and others, so that to-day the diagnosis of the site of an injury to, or lesion of, the brain is quite precise. A similar interplay of medicine, pathology, and physiology is seen in the development of our knowledge of the functions of the thyroid gland. Work such as this and other recent advances in treatment based on joint clinical and experimental investigations serves to show the importance of co-operation between clinicians and experimentalists.

A MEMORIAL tablet to Sir Humphry Davy has just been unveiled in the Pump Room of the Wirer Endowment at Ischl in Austria, to commemorate his stay at that watering-place. The ceremony was performed in the presence of a distinguished party, including the Austrian Chancellor, Dr. Streeruwitz, who in a speech dwelt upon the gratitude the world owes to the inventor of the miner's safety lamp. It was on May 26, 1818, that Davy embarked at Dover for Naples, whither he was going to study the problem of unrolling the papyri found at Herculaneum. His journey took him up the Rhine and Danube into Austria and Hungary, and on this journey he took the opportunity of making observations of the formation of mists over rivers and lakes, which at that time was not understood. The rivers he studied included the Inn, the Ilz, the Raab, the Save, the Ironzo, the Po, and the Tiber, his results being contained in his paper to the Royal Society of Feb. 25, 1819, entitled "Some Observations on the Formation of Mists in Particular Situations".

THE scientific work of the Czechoslovak biologist, J. E. Purkyně (Purkinje), like that of many other pioneers, has largely escaped attention, although a number of men of science have, from time to time, referred to the importance of his contributions to many branches of biology. Purkinje was born near Prague on Dec. 17, 1787, and died there on July 28, 1869, and on the occasion of the sixtieth anniversary of his death, Dr. O. V. Hykeš has collected and issued in pamphlet form ("Přírodovědecké práce J. E. Purkyně") a selection of comments and appreciations of his work by well-known biologists. Purkinje's researches cover subjects in microscopic anatomy, cytology, neurology, the physiology of vision and of the ear, biochemistry and anthropology. An American writer in 1899 declared that Purkinje, under the most unfavourable conditions, had laid the foundations for modern physiology. Although the compound microscope had been in use for nearly a century, his discoveries, up to 1830, were made with the aid of simple lenses, yet he was the first to use the microtome. When unable to pursue a subject exhaustively, Purkinje time and again pointed the way to a noteworthy discovery. He was the first to employ the term protoplasm and to establish the identity of structure in plant and animal cells. Purkinje's work has hitherto attracted most attention in Germany and Scandinavia.

IT is generally recognised that while many local museums include a number of objects illustrating the life of the population of the area in medieval and later times, an urgent need is a national museum for England which will illustrate the traditional arts, industry, and life generally of the folk. Wales already has a national museum of this character, and there are similar collections in Ireland and Scotland. The matter is undoubtedly one of some urgency, as objects of the character contemplated are becoming more and more difficult to obtain every day. The council of the Royal Anthropological Institute, having these facts in view, has appointed a small committee to consider the position. Lord Onslow, Sir Henry Miers, and Dr. R. E. Mortimer Wheeler have accepted appointment to the committee. The Royal Society, the Zoological Society, the Society of Antiquaries, the Folklore Society, and other interested bodies have nominated, or have been invited to nominate, representatives to sit on the committee. It is hoped to hold a conference to discuss ways and means early in the autumn.

A COMMITTEE has been formed to establish a Memorial Fund with which the name of the late Prof. L. T. Hobhouse may be permanently associated, to be used to assist in the perpetuation of his influence. The committee consists of Prof. S. Alexander, Sir William Beveridge, Mr. Victor Branford, Dr. Morris Ginsberg, Dr. G. P. Gooch, Mr. J. L. Hammond, Mr. J. A. Hobson, Prof. Gilbert Murray, Prof. Percy Nunn, Sir Herbert Samuel, Mr. C. P. Scott, Sir Hubert Llewellyn Smith, Sir Arthur Steel-Maitland, Prof. Graham Wallas, and Mrs. Beatrice Webb, and subscriptions may be sent to Dr. G. P. Gooch, 76 Campden Hill Road, London, W.8. It is hoped that subscribers may leave it to this widely representative committee to frame a scheme for the memorial and to decide at a later date whether the fund raised can be best used for a lectureship, scholarship, or the publication of studies in the social sciences. Dr. Morris Ginsberg, London School of Economics,

Aldwych, W.C.2, has agreed to act as honorary secretary of the Fund.

AN interesting suggestion for a possible origin of early Mesopotamian culture is put forward by Mr. Henry Field, of the Field Chicago Museum, in the *Times* of July 17. As a result of recent archæological survey work conducted by the Marshall Field North Arabian Desert Expeditions, it would appear that the North Arabian and Syrian deserts, which in palæolithic times were well watered, then supported a considerable semi-nomadic population, of which traces have been found in the form of palæolithic implements on several hundred sites. These range from Upper Chellean, found *in situ* at a depth of 11 feet 6 inches, to Upper Palæolithic. It is suggested that at about the time of Cro-Magnon man in western Europe, the desiccation of the North Arabian area began, and finally drove the population, by that time in a neolithic stage of culture, westwards to the Nile Valley and eastwards to Mesopotamia, where they constituted the earliest inhabitants. On the evidence of the earliest skeletal remains found in the lowest levels of Kish, it would appear that the earliest inhabitants of that area may well have been direct descendants of the Palæolithic and Neolithic peoples of the North Arabian desert.

PROF. S. LANGDON, who forwards Mr. Field's letter to the *Times*, adds a much-needed caveat. While recognising the importance and the significance of the discovery of this extensive palæolithic culture of the Syrian desert, he hesitates to accept it as the source of Sumerian or prehistoric Mesopotamian culture. As he points out, it raises the question whether this culture is to be attributed to the Sumerians of Elam and of Central Asia and of the Indus Valley or to the Semites of Akkad. The excavations at Kish and Jemdet Nasr appeared to have settled this question definitely in favour of the proto-Sumerian Elamite people. Prof. Langdon emphasises the significance of the fact that while no painted pottery has been discovered in the Syrian desert within 2000 years of the date of that at Kish, in Elam and Central Asia, at water level at Kish and at plain level at Jemdet Nasr, the painted ware is accompanied by epigraphical material, seals and copper of undoubted Elamitic affinities which would all point to the proto-Sumerians of the east as the founders of this civilisation. Mr. Field's interesting suggestion may well serve to throw light on the early migrations of the Semitic peoples. It fails to withstand the weight of the evidence to which Prof. Langdon refers, which is all against a Semitic origin for the earliest culture of Mesopotamia.

THE following elections have been made to Beit Memorial Fellowships for Medical Research, the place of research being given in brackets: *Fourth-year Fellowships* (value £500 per annum): Mr. R. J. Lythgoe and Mr. M. W. Goldblatt. *Junior Fellowships* (value £400 per annum): Mr. R. Hill, to investigate the specificity of hæmoglobins and the properties of cytochrome (Biochemical Laboratory, Cambridge); Dr. Ann Bishop, to complete the study on which she has been engaged during last two years of the morphology and development of *Trichomonas* of man and monkeys (macaques) in culture and to investigate other intestinal protozoa (Molteno Institute for Parasitology, Cambridge); Mr. C. L. Cope, to study the diuretic responses of normal and pathological kidneys in man to tubule diuretics (Department of Medicine, Oxford University); Dr. L. E. Bayliss, to study the metabolism of the isolated heart and kidney by means of the heart-lung and heart-lung-kidney preparation and by means of the artificial oxygenator of Bayliss, Fee, and Ogden (Department of Physiology and Biochemistry, University College, London); Dr. W. P. Kennedy, to investigate the function of the ovary (Physiology Department, Edinburgh University, and Royal Infirmary, Edinburgh); Mr. E. Boyland, to investigate the mechanism of carbohydrate metabolism, with particular reference to the phosphoric esters of yeast and muscle (Lister Institute, London); Mr. E. M. Case, to study the metabolism and thermodynamics of muscle by means of a comparative study of alcoholic fermentation by yeast and lactic acid production by muscle, and by means of a new apparatus to investigate the thermal properties of so-called 'non-irritable' muscle, concurrently with chemical analyses (Sir William Dunn Institute of Biochemistry, Cambridge); Mr. K. A. C. Elliott, to undertake studies on biological oxidations such as the oxidation of metabolites by various thermolabile and thermostable peroxidases (Biochemical Laboratory, Cambridge); Miss M. H. Roscoe, to continue investigations on the distribution of the antipellagra vitamin B2 in natural foodstuffs and a comparison with the distribution of the anti-neuritic vitamin B1 (Lister Institute, London).

IN honour of the sixtieth birthday, on June 27, of Prof. Hans Spemann of Freiburg, a special number (Heft 25) of *Die Naturwissenschaften* has been issued. A portrait of Prof. Spemann precedes an article of half a dozen pages in which Dr. Otto Mangold gives an account of the main lines of Prof. Spemann's work and the results achieved. This is followed by a list of Prof. Spemann's publications from 1895 until 1929, and by a list of important investigations carried out by pupils and collaborators in more or less close relation with their master, and finally by a series of abstracts, by the respective authors, of the memoirs which form the recently published five-volume 'Festschrift' in honour of Prof. Spemann in *Roux's Archiv für Entwickelungsmechanik* (Bände 116-120). This massive 'Festschrift' and the special number of *Die Naturwissenschaften* are well-merited tributes to one who is held in the highest esteem not only for his manipulative skill, his keen powers of analysis and interpretation and his lucid exposition, but also for his great personal qualities.

THE Department of Mines of the Dominion of Canada has issued its customary Annual Report for the year ending Mar. 31, 1928. This report gives evidence of the great advances made in all departments of the Canadian mineral industry. This is sufficiently shown by the fact that the value of the mineral production of Canada has quadrupled since the year 1900. A matter of special interest in this

report is the reference to the memorial tablet erected by Mr. Fenley Hunter of New York City to the late Dr. George M. Dawson, at one time Director of the Geological Survey of Canada. All who either remember Dr. Dawson personally or who appreciate the admirable work which he did for the Canadian Geological Survey will be pleased to learn that this permanent memorial to him has been erected on an exceptionally suitable spot, namely, on the bank of the Liard River, just north of the boundary line between British Columbia and Yukon, in the delimitation of which Dr. Dawson's surveys have played so conspicuous a part.

THE Annual Report for 1927–28 of the Director of the Department of Terrestrial Magnetism of the Carnegie Institution of Washington details very numerous, varied, and important work in the domain of terrestrial magnetism and electricity. The non-magnetic ship *Carnegie* was being prepared for the world-cruise now in successful progress. Owing to this the amount of field work on land was severely curtailed, but the Department carried on land observational work at its two important observatories at Huancayo, Peru, and Watheroo, Western Australia. In addition, many interesting investigations, both experimental and theoretical, were made in regard to problems of atomic magnetism, terrestrial magnetic variations, wireless propagation, the high-frequency permeability of iron, and other related topics.

IN order to centralise and arrange a methodical plan for the scientific work which is carried on in northern Norway, Svalbard, Jan Mayen, and the Arctic Sea, a Central Committee for the Scientific Institutions at Tromsö has been recently constituted, the statutes for which have now been sanctioned by the Department of Education. According to Northern News Service, the Geophysical Institute at Tromsö will act as a weather-forecasting and aurora observatory, and Prof. Krogness will have the assistance of Prof. Vegard and of other scientific men working in the north, including Mr. Soot-Ryen, who has made valuable researches into the fauna of the coasts of northern Norway. The committee's aim is to forward co-operative work between the different scientific institutions of Tromsö and the north.

ON July 19, Sir Thomas Middleton unveiled at Dishley Grange, in Leicestershire, a memorial to Robert Bakewell (1725–95), the pioneer of stock-breeding. The movement to commemorate the great English farmer was started by Prof. Scott Watson, of the University of Oxford, who had raised money in both Canada and America for the purpose. In his address Sir Thomas Middleton said that the prosperity of the nineteenth century was largely due to improvers, such as Bakewell, in the preceding century, and that his methods had influenced and are influencing stock-breeding throughout the world. Bakewell with great foresight realised that the need of the future was beef and mutton to feed the rapidly increasing town populations, and that this problem could best be met by breeding the right type of stock. Without some new means of providing meat, the industrial expansion would have been impossible. Before his time, animal breeding had been carried on in a haphazard fashion with no definite aim behind it, and it was due to the fact that Bakewell started with a clear objective that his enterprise met with such success. His aim was to obtain animals that weighed heaviest, matured earliest, and most quickly repaid the food they consumed. He obtained his best results with sheep, but also applied his principles to the breeding of cattle, cart-horses, and pigs. The prices he secured for the letting of improved sires testify to the esteem in which he was held by other farmers of his day, and the wide application of his methods by others shows that he is rightly to be considered one of the greatest agricultural pioneers of the eighteenth century. After unveiling the memorial, Sir Thomas Middleton placed a laurel wreath on Bakewell's tombstone, which lies in the ruins of the old church.

MR. JOHN PATTERSON has been appointed Director of the Meteorological Service of Canada, in succession to Sir Frederic Stupart, who retired at the end of June, after fifty-seven years' service.

PROF. F. A. E. CREW, of the Animal Breeding Research Department of the University of Edinburgh, has been elected a foreign member of the Czechoslovak Agricultural Academy.

IN view of the long-continued drought in Great Britain, the Ministry of Health has issued a "Memorandum on Water Shortage", suggesting that water authorities should lose no time in scrutinising the position and considering whether any supplementary supplies are available in their neighbourhood. Suggestions are also made for conserving existing supplies by detection and prevention of waste, temporary reduction or intermission of discharges of compensation water, and use of alternative supplies, if any. It is considered that restriction of the supply for domestic use should be resorted to only in cases of actual necessity.

THE following appointments have recently been made by the Secretary of State for the Colonies in the Colonial Agricultural Services: Mr. W. H. Edwards, lecturer in entomology and zoology at the College of Agriculture, and acting botanist and mycologist, Mauritius, to be entomologist, Jamaica; Mr. S. M. Gilbert, superintendent of agriculture, Nigeria, to be assistant director of agriculture, Trinidad; Mr. A. Pitcairn, district agricultural officer, Tanganyika, to be assistant director of agriculture, Cyprus; Mr. J. R. Mackie, superintendent of agriculture, Nigeria, to be deputy assistant director of agriculture, Nigeria; Dr. R. H. Le Pelley, to be assistant entomologist, Kenya; Lieut. J. Eaden, to be assistant manager, Experimental Fruit Farm, Sierra Leone; Mr. H. E. Green, to be inspector of plants and produce, Agricultural Department, Gold Coast; and Mr. E. Lawrence, to be district agricultural officer, Nyasaland.

A RECENTLY issued catalogue of Messrs. Francis Edwards, Ltd., 83 High Street, Marylebone, W.1, is No. 516, giving particulars of nearly 800

second-hand works relating to the Far East, *i.e.* Japan, China, Korea, Formosa, Siam, Philippine Islands, and the East Indian Archipelago.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An assistant master, to teach engineering, at the Rochester Technical Institute and Junior Technical School—The Principal, Technical Institute, Rochester (Aug. 3). A temporary pathologist in the Public Health Laboratories of the County Council of the West Riding of Yorkshire—J. C. McGrath, County Hall, Wakefield (Aug. 3). A lecturer in mathematics in University College, Nottingham—The Registrar, University College, Nottingham (Aug. 5). A university librarian of the University of the Witwatersrand, Johannesburg—The Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, Trafalgar Square, W.C.2 (Aug. 10). A head of the Engineering Department of the Smethwick Municipal College—The Director of Education, 215 High Street, Smethwick (Aug. 12). A lecturer in agricultural botany at Armstrong College—The Registrar, Armstrong College, Newcastle-upon-Tyne (Aug. 17). Temporary assistant chemists at the Government Laboratory—The Government Chemist, Clement's Inn Passage W.C.2 (Aug. 17). Women senior lecturers in botany and microbiology, physics, zoology and physiology, and a lecturer in domestic science, at Huguenot University College, Wellington, Cape Province—The Registrar, Huguenot University College, Wellington, Cape Province, South Africa (Oct. 1). An experimental assistant at the Air Defence Experimental Establishment—The Superintendent, Air Defence Experimental Establishment, The Aerodrome, Biggin Hill, near Westerham, Kent. A woman lecturer in geography or biology with mathematics (subsidiary) at the Bishop Otter Training College for Women Teachers, Chichester—The Principal, Bishop Otter Training College, Chichester. A woman with training in pathology, biology, or physiology, and interested in poultry, for poultry research—laboratory and field work—at the Wellcome Physiological Research Laboratories—The Director of the Laboratories, Langley Court, Beckenham.

Our Astronomical Column.

Large Meteors.—An illustrated article by James Stokley, issued by Science Service of Washington, D.C., describes some of the largest meteor falls on record. There is a striking illustration of Meteor Crater, Arizona, which is 4000 feet in diameter, and strongly resembles one of the smaller lunar craters. It is now generally agreed, from the age of the trees on its rim, that this was formed by the fall of a gigantic meteor, not less than seven centuries ago. A sketch of an equal area located among the sky-scrapers of New York shows what enormous damage might be done by such falls if they came in populous districts. The largest in modern times fell in the Yenisei Province of Siberia on June 30, 1908, when the area affected was 40 miles in diameter; there was great destruction of animals and trees.

Prof. Charles P. Olivier, who is the director of meteoric observation in the United States, is quoted as saying that most of the meteors observed are moving in hyperbolic orbits. This evidently implies a much greater excess over the parabolic velocity than is found in the case of comets; the excess in these is too slight to be detected in the comparatively rough determinations that are alone possible for meteors. Hence the meteors having such speeds cannot belong to the solar system, but are merely passing through it, having had their origin somewhere in the region of the stars.

Dr. W. J. Luyten, stationed at the South African branch of Harvard College Observatory, reports that the great mass of iron recently found in that region is a genuine meteor; he estimates it at 50 tons, which would make it the largest meteoric mass known. The Ahnighito meteor, now in New York, weighs $36\frac{1}{2}$ tons.

Curvature of Space.—The *News Service Bulletin* of the Carnegie Institution of Washington, No. 13, contains an article by Dr. E. P. Hubble describing the further work of Mr. M. Humason and Dr. F. G. Pease at Mt. Wilson Observatory on the radial velocities of spiral nebulæ. Note has already been made in this column of their conclusion that the apparent velocity of recession is proportional to the distance of the object, and is thus evidence of the truth of de Sitter's deduction from the theory of relativity that remote objects should have a displacement of their spectral lines towards the red.

A few months ago the highest velocity found was that of the nebula N.G.C. 7619 in Pegasus, the distance of which was estimated as 25 million light-years; it appeared to be receding at the speed of 2400 miles per second. By using very long exposures, extending to 40 hours, the spectra of three nebulæ in a cluster in Coma Berenices, near the pole of the Galaxy, have now been photographed. The distance of the cluster was estimated, by methods already described, as 50,000,000 light-years; the speeds of recession found are 4900 miles per second for N.G.C. 4860, 4600 miles for N.G.C. 4853, and 3100 miles for N.G.C. 4865. The first two support the theory of speed being proportional to distance; the third does not fit so well. Observations of other nebulæ in the region are planned; it is considered possible that N.G.C. 4865 does not belong to the cluster, but is a small nebula at a less distance.

Period of the Lyrid Meteors.—Mr. Maltzev of Leningrad has been investigating the Lyrid meteoric shower and finds a period of 29·70 years to accommodate satisfactorily some of the observations. He inquires as to where details can be found of the rich display which occurred in 1863, but there seem to be very few accounts of it. However, in the B.A. Report for 1863, p. 325, there is a note on the phenomenon by Prof. H. A. Newton which may be of some use. Mr. W. F. Denning writes that he has tried on several occasions in past years to deduce a period for the shower and found 16·1 years and 29·65 years will conform with a number of the most striking displays. He does not, however, regard them as having a perfectly satisfactory application, for they do not accommodate the various showers in 1803, 1851, 1863, and a few other returns. We require more data, and this may only be obtained by careful watches of the shower in future years. Its exhibitions during the past half a century have generally been somewhat feeble.

Research Items.

A Novel Theory of Animal Evolution.—The problem presented by the inter-relationships between the major groups of animals has been the chief stumbling-block in the path of all theories of evolution. The enormous differences between these groups as they exist to-day make a linear evolution difficult to understand, and the difficulty is increased when it is realised that, so long ago as Middle Cambrian times, the inter-relationships between the different invertebrate phyla were just the same as they are to-day. Austin H. Clark therefore suggests that at the very outset all the numerous phyla came into being not successively but simultaneously by following different paths of development from the single cell—and to this theory he gives the name primagenesis (*Jour. Washington Acad. Sci.*, vol. 10, June 1929). The abrupt discontinuities suggest that each of the phyla represents a re-combination of characters inherent in animals as a whole in a form capable of meeting the requirements of animal existence, both in internal balance and in external contacts. Apparently the focal points at which a balanced condition capable of survival and of meeting competition is attainable are rather few and are well separated from each other, for each of the phyla is widely different from the rest. The flat picture of animal life presented as a result of primagenesis serves as the ground from which various evolutionary trees, one for each phylum, rise upwards through geological time.

Mental Defectives and their Order of Birth.—Two commonly accepted theories tend to place the mentally defective child either at the beginning or at the end of the family succession. That the defective child is the first born infers that mental deficiency is a result of birth trauma ; that it is the last born suggests the result of an exhaustion process. To test these popular notions, Neil A. Dayton has made a survey of 10,455 retarded children in the public schools of Massachusetts (*Jour. Heredity*, vol. 20, May 1929). In order to avoid the possibility of mixed classifications so far as intelligence was concerned, the retarded children examined were divided into two groups by sex, those with an intelligence quotient above and those below 0·70. Relatively twice as many boys (6671) as girls (3739) figured in the examinations. The families analysed contained from two to ten or more children, and the results showed no uniformity. That is to say, there is no evidence that the feeble-minded child tends to be either first or last in the family. If anything, there appears to be a slight tendency for the feeble-minded to occur in the middle of the family, particularly in the larger families. Families having a mentally defective child are larger than families having a retarded child.

Herring Research at Cullercoats.—The Report of the Dove Marine Laboratory, Cullercoats, Northumberland, for the year ending June 30, 1928, drawn up by the Director, Prof. A. Meek, shows a satisfactory progress in the work done, which is mainly the continuation of herring investigations by Mr. B. Storrow, assisted by Mrs. Cowan. Mr. Storrow deals with the shoals involving the examination of some 4000 fish from England, Scotland, and Ireland, and, in addition, about 3000 local fish were examined, and data relating to size, sex, maturity, with scale and age records, were sent to the Ministry of Fisheries. The work on herring shoals was begun in 1919, and an unbroken series of data has been secured up to the present time. In the Yarmouth fishery the 1922 year class with five winter rings is still very abundant, although it has been fished since 1925, which fact points to the original wealth of this year class noted in previous reports and predicted from the presence of young fish in spawning shoals in 1922. In 1927 there were unprecedented numbers of young mature fish with two winter rings, and the product from this spawning may be expected in 1931 in the British fishery. An important point noted in the 1928 local herring is the change in quality. In the previous year many complaints were heard as to the poor quality of the fish taken all along the coast. The season of 1928 shows a considerable difference, the fish having a large amount of fat in the body cavity, the flesh being whiter and the body plumper, with a thicker back than has ever been observed in these north-east coast herring during the past eighteen years. These are more like the celebrated ' west coast herring ' and are splendid eating. Hopes are expressed that biochemical investigations should be undertaken with regard to these changes. In connexion with the scheme of co-ordinated research with the Ministry of Agriculture and Fisheries, Mr. Gill gives a report on the general hydrographical condition of the Northumberland coastal waters in 1926–28.

Protein Metabolism in Plants.—In view of the general interest of biologists and biochemists in protein metabolism, a critical review of our knowledge of nitrogen transformations in plants by Miss M. E. Robinson (*New Phyt.*, **28**, 117-149) serves a very useful purpose. The author emphasises the uncertainty which surrounds even the primary problems in this field, such as the rôle of light in protein synthesis. In the discussion of this question, an interesting fact is recorded. Abderhalden and Rona showed that *Aspergillus* could produce α-amino acids from nitrate and sucrose in the absence of light, while Bayliss remarked on the absence of cyclic compounds in these experiments. Now Miss Robinson states that tryptophane and histidine are formed under these conditions, though doubting whether it is wise to apply such results to higher green plants where light and chlorophyll may be more important. The claim of Hanning that Cruciferæ embryos can synthesise protein in cultures containing peptones and sugars serves as an example of the interesting possibilities opened up by the application of the methods of tissue culture to metabolic studies.

Bourne or Gypsey Flows.—Intermittent streams occur on dip slopes in chalk country, usually after long continued and heavy rains. They are known by different names in various parts of England, lavants in Sussex and Hampshire, nailbournes in Kent, and gypseys in the East Riding. Various theories have been given to explain their origin. In a paper in *Geography* for June, Mr. J. H. Brown describes these streams and discusses the causes of their flow and intermittency. He finds that the determining cause is the existence of underlying gault clay. Normally the rainfall can drain away through the porous chalk, but exceptional rainfall cannot drain in this way. The impervious gault clay holds it until the lower layers of the chalk are saturated. The water table rises, and where the plane intersects the valley slope a spring marks the start of a bourne. Thus a bourne may flow some months after heavy rainfall owing to a comparatively light fall which brings the water table high enough to cut the slope. There is thus no underground channel at the head of these streams. Mr. Brown gives a number of details of various bournes and discusses the reasons for the gradual decrease in their frequence

of flow, which he associates with the lowering of the gault outcrop by denudation.

Temperature Changes in the Lower Atmosphere.—*Geophysical Memoirs*, No. 46, of the Meteorological Office, is devoted to "A Study of the Vertical Gradient of Temperature in the Atmosphere near the Ground", by N. K. Johnson (London: H.M. Stationery Office, 1929. 3*s*. 6*d*. net). It describes the construction, use, and results of an apparatus for measuring the temperature at three levels up to 17 metres from the ground. In the discussion, special prominence is given to the daily variation of temperature. In 1915, G. I. Taylor discussed this daily variation, using the Eiffel Tower observations, and assuming that the changes of temperature were due mainly to eddy conduction; but in 1925, S. Chapman showed that in the early morning the air temperature at certain levels on the Eiffel Tower was increasing when eddy conduction would act so as to reduce it; he therefore suggested that the temperature changes were largely influenced by long-wave radiation. This result was criticised at the time, doubt being cast on the value of the Eiffel Tower observations. N. K. Johnson concludes that his observations lend strong support to the conclusion derived by S. Chapman. A further contribution to the subject is made by D. Brunt (*Proc. Roy. Soc.*, A, **124**, 201; 1929), who criticises and modifies the equation of eddy conduction introduced by G. I. Taylor and hitherto generally used; D. Brunt also adds a new term expressing the rate of transfer of heat by radiation.

Drilling for Oil with Diamond Drills.—Of recent years a great deal has been written concerning the advantages of employing the diamond drill on oil-fields, especially for accurate exploratory work. Experience has shown, however, that the diamond drill cannot compete with rotary or standard tools under conditions of ordinary routine production drilling, but this does not detract from its value and application in other circumstances. The diamond drill is invaluable for providing geological information, owing to the continuous cores of rock obtainable by its use; such cores, properly taken, record accurately changes in the formations penetrated, thicknesses, dip, and other structural details; thus, as a test of subsurface structure, the system is probably without parallel. Another useful feature of the diamond drill is its ability to deepen rotary or cable-tool wells the diameters of which have been reduced to the minimum to which those systems have been effective; possibly its employment in the latter connexion has been more commonly sought than in cases of purely exploratory drilling. A thorough account of the diamond drilling system from the engineering point of view was given to the Institution of Petroleum Technologists recently by Mr. G. Haseldin, who based his observations largely on the behaviour of this plant in Algeria, the Punjab, and Assam. It is worthy of note that only a short time before the reading of this paper, Mr. R. T. Banks dealt with the advantages of this system of drilling in the high-pressure gas field of Turner Valley, Alberta, Canada (*Canadian Mining and Metallurgical Bulletin* for February), and recorded the attainment there of a hole more than a mile deep in one instance, also the significant fact that in this field, with only one exception, the diamond drills are operating on wells that have had to be abandoned, for some reason or another, by rotary or standard tools.

X-ray Dosage.—After the adoption of the appropriately named 'Röntgen' as a unit of X-radiation at the Stockholm Congress last year, it was found that it was apparently not possible to reproduce it accurately. The discrepancies between the units of different laboratories, of the order of four per cent, although perhaps not important for most therapeutic purposes, were nevertheless unwarrantably large; the matter has been taken up by the United States Bureau of Standards, and a report upon the problem has now been published in the form of a *Research Paper* (No. 56). It was found immediately that, for accurate work, an X-ray bulb had to be supplied with power from a direct current source of high potential. Precise details of how this can be best effected are given in the report, together with a useful photograph showing the general assembly of the generator. Even then, different saturation currents were recorded if a given ionisation chamber was used with different arrangements of the internal electric fields, and it was finally found to be desirable to resort to a null electrostatic method of measurement, the substantial accuracy of which was shown by the agreement of the results with those obtained by direct measurement with a galvanometer, in cases where the latter instrument could be applied. The error in determining the volume of ionised air has not yet been studied, but apart from this, the accuracy obtainable in the measurement of dosage is now claimed to be one per cent or better.

Sulphur Monoxide.—Prof. V. Henri and F. Wolff have described the production and partial analysis of a new band spectrum associated with sulphur in a recent paper in the current volume of the *Journal de Physique* (p. 81). It appears when a heavy oscillatory discharge is passed through the vapour of sulphur dioxide, extending from about 4000 A. to 2500 A., and has been ascribed to sulphur monoxide, the chemical preparation of which has already attracted considerable attention during the last few years. The usual information concerning the molecule has been deduced from the fine and coarse structure of the bands; the oxygen and sulphur atoms are 1·34 A. apart, and their heat of dissociation is 148 kilocalories per gram-molecule, or a little more than half the heat of dissociation of sulphur dioxide into atoms. The excited molecule of the monoxide appears to be formed directly from the dioxide by electronic impact. Prof. Henri has included some theoretical considerations of a general nature in this paper, pointing out in particular the need for the accumulation of data for the vibrational constants of polyatomic molecules in relation to their structure.

Combustion in Electrical Discharges.—The study of the combustion of carbon monoxide and oxygen in the glow discharge which G. I. Finch and D. L. Hodge have published in the June number of the *Proceedings of the Royal Society* has brought to light some interesting facts concerning the part played by the metal of the cathode. Atoms from the surface of the latter pass into the gas under the influence of the discharge, some metals disintegrating in this way more rapidly than others, and it has now been found that in certain circumstances there is a close parallelism between the rate at which this so-called 'sputtering' takes place and the rate of combustion of the gas in the neighbourhood of the cathode. The metal atoms present in the gas evidently facilitate the union of ions of carbon monoxide and of oxygen, and the picture which is presented of their action is one in which they effectively eliminate the mutual electrostatic repulsion of the ions by forming neutral metal-gas complexes. The evidence upon which this view is based is not merely qualitative, but includes the quantitative correlation of the main facts that have been collected for cathodic combustion on one hand and sputtering on the other, good agreement between the two being obtained on the basis of a few simple

assumptions. Combustion can occur elsewhere in the discharge under the appropriate conditions, and can be accelerated by other means, and the influence of moisture upon its course is to be reported upon later.

The Budde Effect in Bromine and Chlorine.—The effect of water vapour on the Budde effect in chlorine and bromine from which all impurities have been removed has been investigated by G. B. Kistiakowsky, whose results are described in the *Journal of the American Chemical Society* for May. The temperature changes of the gas on exposure to illumination were measured by both a glass manometer and a platinum resistance thermometer. It was found that no change in the Budde effect could be detected on drying or moistening pure chlorine and bromine. Attempts were made to test the dryness of the chlorine by mixing with hydrogen, in order to see if the mixture was inactive on exposure to light. It appears, however, that dry mixtures cannot be prepared in Pyrex glass, owing to the formation of water by reduction of the glass by hydrogen at the temperature of sealing.

Laminated Glasses.—The *Journal of the Society of Glass Technology*, vol. 13, No. 49, contains an interesting account by W. R. Lyttleton of the history, development, and methods of manufacture of laminated glass, which is rapidly growing in importance for use in the motor industry. Such glass consists of alternately hard and plastic laminæ welded together into one whole, and has the property of not allowing splinters to fly when it is subjected to a violent blow. Generally, either nitro- or acetate-cellulose is employed as the central plastic medium in this type of glass. The surfaces of the glass and celluloid are carefully cleaned, and in some cases the glass is coated with gelatine or cellulose varnish, before they are united by pressure. If gelatine is used as the central sheet instead of celluloid, it must be hermetically sealed between the glass sheets in order that it may retain its moisture content, without which it becomes brittle. The chief difficulties to be faced in the production of these strengthened glasses are discoloration with time and strains set up by unequal expansion of the laminæ.

Critical Temperature Measurements on Carbon Dioxide in Small Capillaries.—As a result of measurements of adsorption of carbon dioxide in silica gel, both above and below the critical temperature, it has been suggested that liquid exists in the pores of the adsorbant above the critical temperature. If this conclusion is correct, then it would appear that some increase in critical temperature should be observed in very fine glass capillaries, even though the diameters of such capillaries are much greater than those of the pores in silica gel. An attempt to determine the effect of capillary diameter on critical temperature is described by H. T. Kennedy in the *Journal of the American Chemical Society* for May. The critical temperature of carefully purified carbon dioxide was measured in capillaries ranging from 2 mm. to 0·004 mm. in diameter and was found to be independent of the size of the tube. The value obtained for the critical temperature, which is defined as the highest temperature at which a sharp meniscus can be seen by transmitted light in the field of a microscope, was $30{\cdot}96° \pm 0{\cdot}01°$. It is suggested that the discrepancies obtained by various workers are due to the different criteria employed to define the critical temperature.

Existence of Free Methyl.—In a recent number of the *Berichte der Deutschen Chemischen Gesellschaft* (**62**, 1335; 1929), Messrs. Paneth and Hofeditz bring forward evidence of the rather transient but definite existence of the simplest hydrocarbon radical, methyl, in the free state. This result was obtained in the course of an investigation of the mechanism of the reaction involved in the production of metallic hydrides by means of a spark discharge, a reaction which appears to necessitate the presence of a hydrocarbon. Carefully purified lead tetramethyl is volatilised in a current of pure hydrogen or nitrogen at a low pressure in a quartz-tube and at a rather low temperature. When the tube is heated with a Bunsen burner, a lead mirror is deposited and an active gas passes on, which is capable of completely volatilising a second deposit of lead previously made in the same way at a point farther from the supply. Lead tetramethyl is apparently reformed, since it in turn can be decomposed in the same way. Moreover, the distance between the mirror which is being deposited and that which is being removed may be so much as 30 cm. and the space may even be cooled, but the effect falls off very rapidly as the distance is increased. Numerous check experiments were carried out in order to show that the volatilisation of the lead is not due to the action either of hydrogen or of any of the following possible by-products: methane, ethane, acetylene, or ethylene; and the authors claim to have proved that the methyl radical is present in the decomposition product of the methide. Preliminary measurements of the rate of volatilisation indicate that the reaction is approximately monomolecular and that the 'half-life period' of the methyl in an atmosphere of hydrogen at 2 mm. pressure is about 0·006 sec. Similar effects have been obtained with bismuth trimethyl, whereas the methides of antimony and zinc both gave disappointing results. Further, it has been shown that both lead and bismuth can be volatilised as methides by the vapours from the decomposition of either lead-tetramethyl or bismuth-trimethyl. It is essential that all materials should be highly purified beforehand.

Strength of Carbon Steels for Boiler Construction.—Special Report No. 14 on Engineering Research issued by the Department of Scientific and Industrial Research (London: H.M. Stationery Office) describes work carried out at the National Physical Laboratory by R. G. Batson and H. J. Tapsell. The object of the work was to provide information regarding the tensile properties and, particularly, the limiting creep stress of low carbon steels for boiler and superheater tubes, and superheater and steam drums. Results of tests carried out at temperatures up to, in some cases, 650° C. on the limiting creep stress in tons per square inch are given for three steels containing respectively 0·10, 0·17, and 0·22 per cent carbon. The last of these materials, which is representative of steel supplied for superheater and steam drums, had a limiting creep stress of 14 tons per sq. in. at 400° C., 9 at 450°, 5·5 at 500°, and 3·5 at 550°. The two lower carbon steels at 500°, 550°, and 600° C. gave creep stress figures of 3·5 and 5·0; 1·2 and 2·2; 0·6 and 1·2 respectively. At 650° C. the 0·17 per cent carbon steel had a creep stress about half a ton per square inch. To prevent oxidation of the specimens, test pieces were coated with a few thousandths of an inch of aluminium by calorising, or with 0·01 inch nickel. It is shown that such protective coatings have no influence on the rate of creep, but provide very good resistance to scaling at the high temperatures. Unprotected samples scaled rapidly above about 570° C., particularly when subjected to excessive straining.

The London School of Hygiene and Tropical Medicine.

THE history of the London School of Hygiene and Tropical Medicine, the new home of which was opened by H.R.H. the Prince of Wales on July 18, goes back to 1921, when a committee appointed by the Minister of Health of that day, Sir Alfred Mond, now Lord Melchett, under the chairmanship of the Earl of Athlone, to report upon the needs of post-graduate medical education in London, advocated among other things the establishment of a central institute of preventive medicine. This recommendation began to bear fruit in the following year, when the Trustees of the Rockefeller Foundation in New York generously offered £460,000 for the building and equipment of such an institute, if the British Government would be responsible for its staffing and maintenance. In the course of their campaign of preventive medicine in all parts of the world, the authorities of the Rockefeller Foundation had arrived independently at the conclusion that a great teaching centre of this nature, with an international outlook, was required if the teachings of hygiene were to be adequately promulgated; and they realised that London, as the capital of the British Empire, the centre of the world's commerce, and the cradle of modern public health administration, would form the ideal site.

Photo.] [*Walshams, Ltd.*

FIG. 1.

Thirty years ago, as is well known, Mr. Joseph Chamberlain, when Colonial Secretary, at the instance of Sir Patrick Manson, founded a school for the study of the diseases of the tropics; and the London School of Tropical Medicine so established, first at the Albert Docks and, since the War, at Endsleigh Gardens, always under the ægis of the Seamen's Hospital Society, has rendered constant service to the Empire. Negotiations with the Seamen's Hospital Society led to the absorption of this school into the new institute; and in August 1924 the resulting "London School of Hygiene and Tropical Medicine", affiliated with the University of London, was incorporated by Royal Charter, a union which serves to emphasise the fact that the fundamental needs of hygiene are the same throughout all climates.

Now that the School is about to take possession of its new premises, it is possible to gauge the magnitude of the task which has been entrusted to the director, Dr. Andrew Balfour. The School consists of six divisions: Public health; epidemiology and vital statistics; bacteriology and immunology; biochemistry (including chemistry as applied to hygiene); medical zoology (including protozoology, helminthology, and entomology); and tropical medicine and hygiene. These divisions will collaborate in providing courses of instruction for the diplomas of hygiene and of tropical medicine and hygiene; independently they will provide advanced teaching in their special subjects; and they will afford ample facilities for research. It has been the constant aim of those concerned with the organisation of the School to secure a nice balance between these several activities, and much of the space available in the building has been so allotted that it may be used for teaching or research as occasion may demand. It

FIG. 2.

is most desirable that men on furlough from the tropics should have somewhere to go where they can finish off any research work that they may have on hand. The services of the library to the man in the tropics, as well as to the worker in Great Britain, will be no less valuable. For, with the collaboration of the Bureau of Hygiene and Tropical Diseases which will be housed in the building, it is hoped to develop something approaching an international information bureau in all subjects within the purview of the school. The museum also, which will be open to the public, will play an important part, both educational and propagandist. It consists of three parts: sanitary engineering, general hygiene, and tropical medicine. Many of the exhibits have been prepared and presented, and will be kept thoroughly up-to-date by large commercial interests concerned in public health activities of various kinds.

The building which is to subserve this varied array of functions is a massive block in Portland stone lying just north of the British Museum (Fig. 1). The successful design was submitted by Mr. P. Morley Horder, and Mr. Verner O. Rees, in association with Mr. Horder, has carried through the execution of the design so submitted; and despite the economy in external ornament, dictated by the practical needs of the building, the architects have succeeded in making a very pleasing contribution to the architecture of Bloomsbury. The building consists of four main stories with a recessed floor above these, and finally a small top floor composed mainly of animal houses. The walls and foundations have been so constructed that they will support another story should this eventually become necessary.

The general plan of the building is that of a letter H, with the long sides on Gower Street and Malet Street, a cross-bar uniting the two and separating the north and south courts, and with the foot of the H closed by the main front which faces south on to Keppel Street. The severity of the Keppel Street elevation is relieved by a wide frieze composed of wreaths and of the names of some of the pioneers in hygiene and tropical medicine; and a lively series of gilded designs, representing some of the animals which concern the hygienist most closely, are set in the metal balustrades below the first floor windows. These ornaments are continued some way along Gower Street and Malet Street, but beyond this the side elevations are relieved only by the prominent entrances. The main entrance, in Keppel Street, is surmounted by a large panel engraved with the handsome seal of the School.

Probably the most striking feature about the interior of the building is the abundant supply of light and air. The passages are considerably wider than is usually the case in a building of this type, and this reflects the intention of the architects to ensure that the School should in no way fall short of those principles which it will be its main function to inculcate. With the exception of the main lecture theatre, ventilation is secured throughout by natural means; the large open courts help to make this possible. The working departments occupy the sides and cross-bar of the H, and the planning of these departments has varied with their respective functions. The base of the H, the Keppel Street front, contains those sections which are of more immediate concern to the outside public; and in this part, naturally, more concession has been made to architectural effect.

Immediately beyond the entrance hall and occupying the south court is the main lecture theatre. It is the easiest part of the building to find; a most convenient arrangement, for this theatre will frequently be used for 'outside' lectures. On the first floor, the entire frontage is occupied by the library, a wide, imposing room, unbroken by pillars, panelled throughout with oak (Fig. 2). Immediately behind the library, access is provided to the flat roof of the lecture theatre, which will be laid out as a garden court. The second and third floors comprise the museum; the lower devoted to hygiene, the upper to tropical medicine, both splendidly illuminated by large windows in the north and south walls and by three open wells admitting light from above.

The opening ceremony was performed by H.R.H. the Prince of Wales on July 18, almost exactly three years after the foundation stone was laid by Mr. Neville Chamberlain as Minister of Health. The Prince of Wales was received by Lord Melchett, chairman of the Board of Management, who read an address of welcome which outlined the history and functions of the School. In his reply, the Prince of Wales stressed the importance of this great benefaction as a sign of Anglo-American friendship, and expressed his belief that the opening of this School would inaugurate a new era in preventive medicine. When Sir Holburt Waring, chairman of the Court of Governors, had returned thanks to the Prince of Wales for his attendance, and had been supported by Sir Gregory Foster, Vice-Chancellor of the University, His Royal Highness visited the various departments of the building. The assembled company was entertained to luncheon as the guests of Lord Melchett, the building was thrown open for general inspection, and a series of kinematograph displays showing some aspects of preventive medicine were exhibited in the lecture theatre. The School achieved a very gay and successful debut, and, given adequate financial support, there is every reason to expect that it has before it a long and prosperous career "in the Service of Mankind".

History of Science Exhibition at Florence.

THE first National Exhibition of the History of Science is being held from May to October of this year at Florence. It is of great interest to those concerned with the story of the development of scientific thought, although this development is somewhat obscured by the grouping of the exhibits according to their local origin rather than in logical or chronological order.

Of the various sections of the Exhibition, perhaps the most important are those in the rooms illustrating the discoveries of Leonardo da Vinci and Galileo Galilei. Here are interesting models of flying machines constructed in accordance with the descriptions in Leonardo's "Codice del Volo degli Uccelli". Among them is a machine to be fitted to the shoulders, and another of a canvas wing, the formation of which, similar to that of a Venetian blind, was imitated from the wing of a bird. Other designs show Leonardo's final device for the motion of the wings, his "macchina volante con piano portante", representing the final perfection of the type. There is also Leonardo's parachute and his instrument devised for the solution of the problem of the Arabian mathematician, Alhazen.

A number of models illustrate the experiments and discoveries of Galileo. There is the inclined plane for testing the rate of descent of bodies, the semiparabola illustrating the path traversed by objects horizontally projected, and the apparatus that illustrates the action of the pendulum. Here, too, are the 'Compasso di proporzione' or 'military compass',

invented by Galileo in 1596, and a photograph of the first lens constructed by him in 1610, with a diameter of 4 centimetres. There are also various astronomical and other instruments of the sixteenth and seventeenth centuries. Thus we have an apparatus for the discharge of projectiles, with pistol and quadrant attached to it, which belonged in 1597 to Robert Dudley, Duke of Northumberland, and a lens of 1690 used by Averani and Targioni for experiments on the action of solar rays on precious stones, and by Donati for the observation of stellar spectra.

The Exhibition contains many first editions and manuscripts of famous scientific works. Among these are Galileo's "Compasso geometrico" printed at Padua in 1606, the MS. of his first draught of the "Sidereus Nuncius", his "Il saggiatore" (Rome 1623), and his "Delle cose che stanno in su l' acqua" (Florence 1612). There is also Galileo's autograph letter in defence of his "Tractate" on the motion of the earth, from the Biblioteca Roncionana di Prato. Among other early editions of famous works is a copy, printed at Florence in 1611, of Kepler's "Narratio de observatis a se quatuor Iovis satellitibus erronibus".

More modern scientific developments are also represented in the Exhibition. There is a case of manuscripts of Galvani (1737–1798), among which is the holograph copy of his "De viribus electricitatis in motu muscolari". The telescope, microscope, and other instruments used by G. B. Amici are shown, with a copy of the famous electromagnetic machine of Antonio Pacinotti and a case of his manuscripts.

The Turin and Milan rooms are mainly devoted to the development of modern engineering. Here is exhibited the Sommeiller perforator, used in the construction of the Mont Cénis tunnel, the first F.I.A.T. automobile of 1899 and material relating to the making of the first Italian railways. There is a case of autograph letters by Galileo Ferraris, the physicist (1847–97), and the original apparatus constructed by him for the study of the rotating magnetic field. The first instruments used by Marconi, including condenser, receiver, transformer, etc., are to be seen. There is also a case of early printed pamphlets relating to aeronautics, among which is Blancard's "Relation du 15me voyage aérien fait à Francfort A.M. le 3 d'octobre 1785".

It is impossible to close an account of this Exhibition without mentioning the very interesting exhibits of the Reale Academia Nazionale dei Lincei. Among these is a series of manuscript volumes of the proceedings of this famous Italian predecessor of the Royal Society. The first volume is dated 1603, the year of the foundation of the Academy by Prince Federigo Cesi. This case contains also the first editions of some notable works by the early Lincei, including the "De nova stella disputatio" by Johan Eck (Rome 1605), the "De aereis transmutationibus", by Giovanni Battista Porta (Rome 1614) and Galileo's "Il saggiatore" (Rome 1623). In another case are the MS. volumes of the proceedings of the Academia del Cimento, dated 1666 and subsequent years.

The Official Guide and Catalogue to the Exhibition can be obtained on application to the Direzione, Prima Esposizione Nazionale di Storia della Scienza, Piazza Cavour, Firenze. S. D. WINGATE.

Long Delayed Radio Echoes.

PRINCIPAL PEDERSEN, of the Technical College, Copenhagen, has communicated a paper in English on "Wireless Echoes of Long Delay" to the physical section of the Danish Royal Society, which shows that scientific workers hold very different opinions on this subject.

Störmer, Pedersen, and Wagner think that the echoes are caused by radio waves being reflected from swarms of electrons out in space, whilst others, van der Pol, Appleton, and Ardenne, assume that the long delay is due to special conditions in the Heaviside-Kennelly layer. To account for the long delay which sometimes occurs before the arrival of the echo, Ardenne assumes that the waves travel round the earth some hundreds of times. Owing, however, to the necessary attenuation, this assumption presents great difficulties.

Principal Pedersen gives a mathematical proof that the long delayed echoes cannot arise either by the propagation of radio waves within the earth's atmosphere or by the waves travelling outside the latter in a medium so strongly ionised that the group velocity of the electrons approaches zero. In his opinion they are due to the fact that the waves have travelled very great distances outside the earth's atmosphere and have then been reflected by swarms or bands of electrons in space, as described by C. Störmer in NATURE (Vol. 122, p. 681, 1928). The assumption is made that all waves shorter than about 8 metres will penetrate into space with very little attenuation. At noon, all waves longer than about 40 m. are completely reflected or refracted back to the earth. At midnight the waves must be longer than 70 m. to be reflected back. The lengths vary appreciably with the ionisation of the upper atmosphere.

It is concluded by Principal Pedersen that echoes occurring after 10 seconds cannot be due to the propagation of waves within the earth's atmosphere. Echoes occurring after intervals of time up to 30 seconds are probably due to propagation along or reflection from Störmer bands. Occasionally echoes do not occur until several minutes have elapsed. In these cases the bands of ions must be outside the space in which the magnetic field of the earth exerts any appreciable direct influence.

University and Educational Intelligence.

ABERDEEN.—The degree of Doctor of Science has been awarded to Dr. A. N. Campbell, for a thesis entitled "The Existence of Liquid Racemates"; Sophia L. M. Connal (*née* Summers), for a thesis entitled "A Particular Study of 55 Species of Mosquitoes met with in Nigeria"; Mr. G. Redington, for a thesis entitled "The Effect of Light on Plant Growth".

CAMBRIDGE.—The Wrenbury Scholarship has been awarded to L. J. V. Shepherd, of St. John's College. Miss A. S. Dale, of Newnham College, has been re-elected to the Michael Foster Research Studentship in physiology. At Clare College the Denman Baynes Studentship has been divided equally between E. C. Bullard and R. M. Margoei.

EDINBURGH.—The Cameron Prize in practical therapeutics has been awarded to Sir Leonard Rogers, in recognition of the discoveries he has made in the treatment of several tropical diseases, and in particular in the treatment of cholera, amœbic dysentery, and leprosy. This prize is "awarded annually to a person who, in the course of the five years immediately preceding, has made any highly important and valuable addition to practical therapeutics".

LEEDS.—Dr. Ll. Lloyd has been appointed reader in entomology and protozoology.

LONDON.—Prof. H. H. Woollard has been appointed as from Sept. 1 to the University chair of anatomy tenable at St. Bartholomew's Hospital Medical College.

Prof. Woollard was educated at the University of Melbourne and at University College, London. From 1919 until 1923 he was senior demonstrator, and from 1923 until 1927 assistant professor of anatomy at University College, London. Since 1927 he has been professor of anatomy in the University of Adelaide. His publications include "Recent Advances in Anatomy" (Churchill, 1927) and "Scientific Basis of Anatomy" (translated from the German; Bale, Son and Danielsson, 1927).

Mr. L. C. Robbins has been appointed as from Aug. 1 to the University chair of economics tenable at the London School of Economics. Mr. Robbins entered the London School of Economics in 1920 and on graduation was appointed research assistant to Sir William Beveridge, and later lecturer in economics. His published work includes numerous papers on the theory of population, the theory of value, and other problems of economic theory.

The following doctorates have been conferred: D.Sc. in Chemistry on Mr. J. E. G. Harris (University College), for a thesis entitled "The Soledon Reaction"; Mr. A. J. Turner, for a thesis entitled "The Relation between Atmospheric Humidity and the Breaking Strengths and Extensibilities of Textile Fabrics before and after Weathering", and other papers; D.Sc. (Engineering) on Mr. Arthur Winstanley, for a thesis entitled "Roof Control when working Coal Seams by Longwall".

The University Studentship in Physiology for 1929–30, of the value of £100 and tenable for one year in a physiological laboratory of the University or of a school of the University, has been awarded to Miss Margaret Hill.

The Chadwick Trustees have made a grant of £500 towards the cost of equipping the new laboratory of the Department of Municipal Engineering at University College, and also a grant of £200 a year for three years to the Department.

APPLICATIONS are invited by the Association of Surgeons of Great Britain, 17 Wimpole Street, W.1, for a surgical scholarship of the value of £350. The object of the scholarship is to enable the holder to pursue a definite line of research or to study surgery in specified clinics, either at home or abroad, and candidates in their applications should state the line of research or study that they propose to pursue. The latest date for the receipt of applications is Sept. 20.

THE Ramsay Memorial Fellowship Trustees have made the following awards of new fellowships for the session 1929–30 at the centres named: British Fellowship, tenable for two years, to Mr. O. H. Wansborough-Jones (University of Cambridge); British Fellowship, tenable for one year only, to Mr. R. J. Phelps (University of Oxford); Canadian Fellowship to Dr. L. M. Pidgeon (University of Oxford); Japanese Fellowship to Prof. Y. Nagai (University College, London); Spanish Fellowship to Don Andres Leon y Maroto (University College, London); Swedish Fellowship to Mr. E. K. Troell (Rothamsted Experimental Station, Harpenden). The Trustees have renewed the following fellowships for the session 1929–30: Dr. H. Bienfait (Netherland Fellowship at the Imperial College of Science and Technology, London), and Dr. P. Maitland (Glasgow Fellowship at the University of Cambridge). Sir Robert Waley Cohen has been appointed vice-chairman of the Trust in succession to Sir John Brunner, deceased, and the Hon. Henry Mond has been appointed a Trustee.

Calendar of Patent Records.

July 28, 1758.—The production of zinc on a commercial scale was first undertaken by William and John Champion, who erected works at Bristol about 1740. John Champion's patent for extracting zinc from blende, a method of manufacture which did not become general until the middle of the nineteenth century, was granted on July 28, 1758. The Bristol works were later transferred to Swansea, which became the centre of the British trade.

July 30, 1571.—Richard Mathew was the first Englishman to make fine cutlery, an art which he had learnt while travelling abroad. On July 30, 1571, he was granted a patent for the "making of certen haftes called Turkye haftes for knyves, weapons, and other things by hym lately devised in our realme to be made of dyvers peces of horne of one or of sundry coloures mixed and garnished betwene those peces with yellow or white plate", but the patent was successfully contested by the Cutlers' Company before the Privy Council on the ground "that it hath been and will be the overthrow of the cutlers within the city".

July 31, 1781.—One of the early competitors for the prize offered by the Paris Academy of Sciences in 1775 for a practicable process of manufacturing artificial soda was Bryan Higgins, whose invention was patented on July 31, 1781. The process did not overcome the difficulty, but this and other early attempts paved the way for Leblanc's successful solution of the problem a few years later.

July 31, 1846.—Lord Armstrong's invention of the hydraulic crane, which was the pioneer in the application of hydraulic power for lifting purposes, and from which evolved the hydraulic elevator, was patented on July 31, 1846. It was first introduced for lifting the stone in a Yorkshire quarry and was rapidly adopted.

August 2, 1695.—On Aug. 2, 1695, there was granted to Daniel Quare, a noted London clockmaker and the inventor of the repeater watch, a patent for "a portable weather glasse or barometer which may be removed or carried to any place though turned upside down without spilling one drop of the quicksilver or letting any aire into the tube". The Clockmakers' Company took exception to the patent and informed its members that anyone who was proceeded against on account of the patent would be defended, but the quarrel must have been of short duration, for Quare became Warden of the Company in 1705 and Master in 1708.

August 2, 1800.—The rifling-machine for guns dates from the patent of Thomas Gill, gunmaker of Birmingham, whose patent is dated Aug. 2, 1800. The barrel is fixed on a reciprocating frame, and the cutters of the required width are attached to a long bar which passes through the barrel and is rotated in centres at each end by means of a rack and pinion mechanism. No record of a machine having been made is, however, known.

On the same day, Aug. 2, 1800, there was granted to Mathias Koops a patent for his newly invented method of manufacturing paper from straw, etc. The patent was voided by the non-enrolment of a specification, but the process is described in a specification enrolled on a second patent formally granted the following year, though Koops petitioned that a specification might be dispensed with. In 1800, Koops published "An historical account of the substances which have been used to describe events and convey ideas", which was printed on paper made from straw and had an appendix on paper made from wood.

Societies and Academies.

LONDON.

Geological Society, June 26.—**R. O. Roberts**: The geology of the district around Abbey-Cwmhir (Radnorshire). This paper deals with an area of about 30 square miles in north-western Radnorshire. The rocks belong to the Bala, Valentian, and Wenlock Series. Only the lowest beds of the Birkhill Stage are exposed, and they are overstepped by the Tarannon Stage, which, over most of the area, rests directly on folded Bala rocks. The Bala rocks are exposed along the north-eastern extension of the Towy anticline; but, in this district, the anticlinal axis is partly replaced by an important strike-fault, which hades westwards. Subsidiary folds may be recognised within the Bala rocks. The axes of these folds are parallel to the general strike of the strata, although there is a change in the direction of pitch around Nantmel. The Bala rocks were folded in pre-Tarannon times, but broad shallow folds in the Tarannon and Wenlock rocks indicate that there has been a repetition of folding along the same lines at different periods.—**C. A. Matley** and **A. Heard**: The geology of the country around Bodfean (south-western Carnarvonshire). The area includes the prominent hill of Garn Bodfean (918 feet above O.D.) and a lesser hill, Moel y Penmaen. Most of the remaining ground is covered by drift. The country can be divided into two belts with reference to the dominant east-north-easterly strike. In the southern belt there is a volcanic series of submarine lavas and tuffs interbedded with ashy and argillaceous sediments. Fossils found at several horizons indicate a Lower Bala age. Garn Bodfean, in the northern belt, consists of a great mass of 'felted' and granular keratophyres and some quartz-keratophyres. It seems possible that the whole hill is a transported mass carried over the Nevin Shales by earth-movements. All the igneous rocks of the area are considered to be extrusive, with the possible exception of a basalt, which may be a sill. A detailed account of the petrography and tectonics of the area is given.—**G. H. Mitchell**: The petrography of the Borrowdale volcanic series of the Kentmere Area (Westmorland). The volcanic rocks are composed of both lava-flows and tuffs of intermediate composition, varying from basic andesites to rhyolites. The rocks are greatly altered, and this has led to difficulty in distinguishing between lava-flows and tuff-deposits, particularly when the former are brecciated owing to flow. The alteration of the rocks, as shown by the changes in mineral composition, together with the materials filling the vesicles, is considered. Much of the alteration may be referred to a variety of propylitisation.

PARIS.

Academy of Sciences, June 17.—The president announced the deaths of Henri Andoyer, Charles Moureu, and Léon Lindet.—**Charles Moureu, Charles Dufraisse, and Joseph Robin**: Researches on rubrene. Study of the mechanism of its formation: description of an intermediate chlorine derivative. In the preparation of rubrene an intermediate compound of the composition $C_{42}H_{29}Cl$ has been obtained by modifying the conditions of the reaction; that this is really an intermediate stage in the formation of rubrene is shown by the fact that it is readily transformed into rubrene without by-products.—**P. A. Dangeard** and **Mme. Mara Lechtova Trnka**: The phenomena of symbiosis in *Myrica Gale*. The tubercles frequently found on this plant are due to a bacterium, for which the name *Rhizobacterium Myricæ* is proposed. Its relations with the cells of the *Myrica* closely resemble those in the tubercles of the Leguminosæ.—**de Possel**: The characteristic invariants of varieties in two dimensions with infinite connexion and the homeomorphy of discontinuous closed ensembles.—**J. Delsarte**: The group of conformal geometry in space of functions of summable square.—**G. Kolossoff**: The extension of a theorem of Maurice Lévy.—**A. Martinot-Lagarde**: An arrangement of an aerodynamic tunnel for the study of flow in two dimensions.—**I. Tamm**: The new theory of A. Einstein and the theory of quanta.—**G. Bruhat**: The notations of thermodynamics.—**E. Sevin**: The introduction of an electric charge vector. Application to the synthesis of the theories of electromagnetism, of light, and of gravitation.—**Pierre Daure**: The photometric study of the Raman effect.—**J. Gilles**: The ultra-violet bands of sulphur.—**Trajàn D. Gheorghiu**: A method of photoelectric photometry with a variable source of radiation. The method described avoids the necessity of using two exactly similar photoelectric cells or absorbent standards, and an ordinary Heraëus mercury lamp can be used as the source of light.—**M. Mathieu**: Crystal constants of the compound $K_2(PtBr_6)$.—**E. Larroque**: The discovery of a Strombus horizon in the island of Djerba (Tunis).—**A. Demay**: The general structure of the Hercynian subdivision.—**Louis Dangeard**: The Bacteriaceæ of the Oolitic iron minerals. The facts observed, while not excluding the possibility of chemical action, confirm the hypothesis that the ferruginous bacteria play an important part in the formation of these iron minerals.—**P. Choux**: The Dideraceæ, Madagascan xerophytes.—**A. Guilliermond**: The development of a *Saprolegnia* in media containing vital colouring matters and the coloration of the vacuome during growth. A comparison of various colouring matters showed that neutral red is very slightly toxic for *Saprolegnia*: this develops nearly normally in the presence of small quantities of this dye which it accumulates in its vacuome.—**E. Chemin**: The variations of iodine in *Trailliella intricata*.—**Jules Amar**: The origin and destination of the cellular fats.—**Paul Dutoit** and **Christian Zbinden**: The spectrographic analysis of the ashes of the blood and of organs. Arc spectra from the ashes of the blood indicate the presence of thirteen elements, including silver, copper, manganese, titanium, and zinc. Examination of the ashes of various organs show a selective action of the pancreas on nickel, cobalt, and lead. The suprarenal capsules appear to retain tin, while zinc is abundant in the liver and kidney. Copper and silver disappear in tumours.—**L. Margaillan**: The regularity of the variations of the characters of oils extracted from a given animal as a function of the point of withdrawal. The fats extracted from tissues taken from various points of *Delphinus tursio* show marked differences in composition. These variations are not irregular, the iodine absorption figure, for example, increasing from the nose to the tail.—**R. Fosse, A. Brunel**, and **P. de Graeve**: The application to urine of the biochemical determination of allantoin.—**E. Doumer**: Osmotic drainage.

CAPE TOWN.

Royal Society of South Africa, May 15.—**A. L. du Toit**: The volcanic belt of the Lebombo—a region of tension. The belt of the Lebombo follows the thirty-second meridian for six degrees and is composed of Karroo Beds disposed in the form of a monocline sinking eastwards beneath the Cretaceous and younger deposits of the littoral. The volcanic rocks of which it is mainly composed consist of a lower group of basalts (and in the north of limburgites and alkaline basalts), a middle one of rhyolites and an upper one of basalts, to a maximum thickness of about 9000

metres. Originating out of crustal tension is a swarm of dolerite dykes, and in the lower group of dykes of felsite and larger linear bodies of dolerite, gabbro and granophyre with north-south trend, regarded as the consolidated feeders of the lavas. Judging from the tilting of these dykes, the growth of the monocline took place during the middle of the eruptive period, seemingly during the Liassic. The crest of the range marks a surface of planation developed during the late Mesozoic and early Cainozoic.

LENINGRAD.

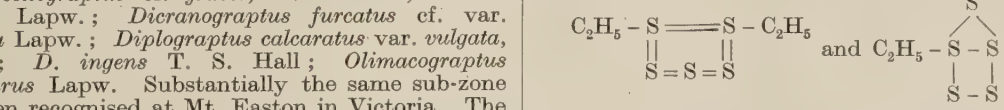
Academy of Sciences (*Comptes rendus*, No. 5).—**P. P. Lazarev and S. Lioznianskaia**: The structure of annealed glass. A description of physical properties including the polarisation phenomena.—**V. I. Vlodavec**: Results of the investigations on the apatite deposits in the Khibin tundras in 1928. The deposits are characterised by the presence of rare earth, particularly of strontium, as well as of phosphorus, fluorine and titanium. Preliminary estimations of phosphorus show that its quantity must be sufficient for an extensive development of a superphosphate industry.—**E. F. Miram**: Contributions to the knowledge of Palæarctic Orthoptera. Descriptions of *Pœcilimon bifenestratus*, sp. n. from W. Caucasus and *Paradrymadusa kiritshenkoi*, sp. n. from Mongolia; the latter species belongs to a genus hitherto known only from Mediterranean countries.—**N. Annenkova**: A new polychæte worm, *Oridia rivularis*, sp. n. from brackish water in the Shantar Islands, in the Okhotsk Sea. Four other known species of the genus occur on sea-shores.—**N. Annenkova**: Corrections and additions to the fauna of Ponto-Caspian Polychæta. Notes on distribution and morphology of a number of species.—**G. Y. Vereščagin and I. P. Sidorytchev**: Some observations on the biology of Comephoridæ. *Comephorus dybovskii* Kor. and *C. baicalensis* Pal., two endemic fishes of Lake Baikal, are not typical deep-water fishes as was supposed previously. The reproductive seasons differ, that of *C. dybovskii* being in February–March, and of *C. baicalensis* in July–August. The food of *Comephorus* was found to consist of an endemic gammarid crustacean, *Macrochetopus branickii* Dyb.

MELBOURNE.

Royal Society, May 9.—**W. J. Harris and R. A. Keble**: A collection of graptolites from the Federal Territory. This is the first collection of graptolites from the Federal Territory. The forms recognised are *Dicellograptus* cf. *gravis*, K. and H.; *D.* cf. *gurleyi* Lapw.; *Dicranograptus furcatus* cf. var. *minima* Lapw.; *Diplograptus calcaratus* var. *vulgata*, Lapw.; *D. ingens* T. S. Hall; *Olimacograptus tubuliferus* Lapw. Substantially the same sub-zone has been recognised at Mt. Easton in Victoria. The British equivalent is the *Dicranograptus clingani*, sub-zone 12, in Elles and Wood's Zonal Distribution (Pal. Soc.).

ROME.

Royal National Academy of the Lincei, May 5.—**U. Cisotti**: Christoffel's second triple tensor and the intrinsic derivation.—**G. A. Maggi**: The potential function of a double layer. (Extract from a letter to T. Levi-Civita.)—**S. Pincherle**: Linear functional operations and developments of the zero.—**A. Bemporad and L. Genovese**: Investigations on the systematic errors of the Draper Catalogue. The errors in this catalogue which can be investigated according to (1) the spectral type and (2) the stellar magnitude are considered, and a table is given for the simultaneous correction of the two errors. Further calculations are being made for a more general treatment of the question, which is of fundamental interest for the photometric reduction of the twenty zones into which the Astrographic Catalogue is subdivided.—**M. La Rosa**: The interpretation of the behaviour of Algol, and the variability of the velocity of light. A further point remaining obscure in the author's ballistic theory of variable stars is examined, namely, the divergence between the theoretical predictions and the behaviour exhibited by Algol and analogous stars, this divergence having been pointed out by Bernheimer and by Salet and used by them as the basis of their denial of the applicability of the ballistic principle to the propagation of light. It is shown that the phenomena presented by such stars actually furnish a striking confirmation of the author's theory.—**U. Bordoni**: Measurement of the thermal conductivity of specimens of irregular shape.—**G. Rovereto**: The tectonic indications of a new railway tunnel of the Ligurian coast.—**L. Petri**: Alterations produced in the stem of papyrus by protozoa. Papyrus growing in Syracuse is subject to various parasitic diseases; one of these, which causes rotting of the portion of the stem immersed in the water, being caused by a flagellated protozoon. The nutriment of this organism consists of the protoplasm and starch granules of the peripheral parenchymatous cells, which it invades by perforating the pecto-cellulosic wall.—**S. Minetti**: Ratio of convergence of Taylorian development.—**S. Cherubino**: Definite or semi-definite polynomes.—**A. Tonolo**: Classification of the surfaces of Hilbertian space, the 2-tangent space of which is of four dimensions (2).—**G. Bacchi**: Decomposition of vectorial hyperhomographs.—**A. M. Bedarida**: The prime ideals of a quadratic body.—**L. Onofri**: The series of powers which assume the circumference of convergence as a singular line.—**L. S. Da Rios**: Curved tubing and wings.—**E. Gugino**: Extension of the theorem of maximum kineto-dynamic effect to the motion of systems with unilateral linkings.—**G. Viola**: Light curve and period of W Ursae majoris.—**U. Barbieri**: Radiotelegraphic determination of longitude, and local attraction in the first order peak Monte Colma di Mombarone.—**R. Brunetti**: Theory of paramagnetism for ions subject to intense molecular action.—**Marya Kahanowicz**: A new series in the spectrum of iron, produced by highly condensed discharges.—**S. L. Straneo**: The functional resolution of the linear problems of the propagation of heat.—**G. R. Levi and A. Baroni**: Diethyl pentasulphides. Two isomeric diethyl pentasulphides are obtainable, their constitutions being probably represented by the formulæ:



The former is probably the isomeride boiling at 119° under 26 mm. pressure and formed by the condensation of sulphur trichloride with mercaptan, and the latter the one having the boiling point 130° and produced by the direct action of sulphur on ethyl disulphide.—**E. Pace**: Condensation of piperonaldehyde with certain pinacolines. The condensation products of piperonaldehyde with the three pinacolines, methyl tert. butyl ketone, ethyl tert. amyl ketone, and propyl tert. hexyl ketone, are described.—**A. Ferrari, A. Celeri, and F. Giorgi**: The importance of crystalline form in the formation of solid solutions (5). Thermal and X-ray analyses of the anhydrous systems, $CoCl_2 - FeCl_2$ and $MnCl_2 - FeCl_2$. The melting points of these anhydrous chlorides, based on those of sodium and potassium chlorides as 803° and 774° respectively, are $722° \pm 1°$ for cobalt chloride, $674° \pm 1°$ for ferrous chloride, and $650° \pm 1°$ for manganous chloride. Ferrous chloride is miscible in all proportions with

each of the other chlorides, and the melting points of the mixtures are intermediate to those of the components, the intervals of crystallisation being so small as to be inappreciable. For the $CoCl_2 - FeCl_2$ mixtures, the angle of the rhombohedron remains unchanged at 60° and the magnitude of the side a varies from 7·05 A. for $CoCl_2$ to 7·155 A. for $FeCl_2$. With the $FeCl_2 - MnCl_2$ mixtures, the angle of the rhombohedron varies from 60° to 61° 25′, the value of a from 7·155 to 7·20, and the ratio $c : a$ from 2·45 to 2·37 in passing from $FeCl_2$ to $MnCl_2$.—**T. G. Levi**: A new class of organic sulphur bases. When an alcoholic solution of aniline is added to a 20 per cent aqueous alcoholic formaldehyde solution into which hydrogen sulphide has previously been passed, heat is generated and 3 : 5-diphenyl – 1 : 3 : 5-dihydrothiazine is formed. Other aromatic amines form similar compounds, and analogous selenium derivatives are obtainable if hydrogen selenide is used in place of hydrogen sulphide.—**Aldo Spirito**: Observations on the regulative processes in relation to the development of the cerebral hemispheres in embryos of Anura (2).—**C. Forti**: Further investigations on the action of certain alkaloids on leucocytes isolated from the organism. Before causing the death of the cell, the hydrochlorides of cocaine, novocaine, and tutocaine give rise to an arrest of its activity, that is, to a suspension of the cellular functions from which recovery is possible. The ease with which these compounds are eliminated or destroyed by the cellular protoplasm varies in degree with the different alkaloids.—**U. Cassinis** and **L. Bracaloni**: Normal alcoholemia during physical exercise. Experiments on eight individuals fail to furnish evidence that alcohol, even in minimal amount, is formed in the blood as a result of muscular work.—**A. Galamini**: The food value of legumes studied with albino rats. When rats are fed solely on raw beans, their urine becomes first neutral and then alkaline, the animals losing weight and dying more rapidly than when fasting. If the beans are cooked, the rats withstand the diet far better, although they lose in weight.—**S. Goldberger**: The action of pH on striated muscle. Experiments made on the lines of Trendelenburg's perfusion method with frog's muscle show that variation in the pH of the liquid (Ringer's) is not accompanied by modification of the latent time. With change of the pH from 5·8 to 9·0, the threshold value, the optimum stimulus, and the magnitude of the muscle contraction alter very little, any slight variations being only gradual. If the pH of the liquid is below 5·8 or above 9·0, the threshold value changes slightly in the first, and diminishes considerably in the second, half-hour, the degree of the diminution being greater in the alkaline than in the acid liquid. As regards the pH in the liquid after the perfusion, with initial pH values between 3·2 and 10·8, the muscle exhibits perfect equilibrating power, the Ringer's liquid having the pH 6·7 after perfusion, even when the experiment is continued for twenty-four hours. With higher or lower pH values, the liquid remains the same after as before the perfusion.—**R. Margaria**: The alkaline reserve of sea-water. Experiments on the capacity of sea-water to fix carbon dioxide indicate that, although the reaction of the water is markedly alkaline, this is displaced, in the perfusion of surviving organs, towards the acid side solely by the presence of the carbon dioxide produced by the tissues and that, considering the pressure of the dioxide existing in the tissues, such displacement might be sufficient to make the pH value less than that of organic liquids. It cannot, however, be assumed that this phenomenon would actually occur, since the tissues have sufficient regulating power to enable them to confer their characteristic reaction on the perfusion liquids.

No. 3118, VOL. 124]

Coal, Iron, and World Peace.

THE subject of Sir Thomas Holland's brilliant and epigrammatic presidential address to the British Association Meeting at Johannesburg, which is printed in the Supplement to this issue of NATURE, is appropriate to the great and varied mineral wealth of South Africa. The address is not an account of the advance of science in the investigation of minerals or of the present stage of scientific opinion as to their genesis ; it deals with their political applications. Its aim is stated in the closing sentences : "Next year the Empire Congress of Mining and Metallurgy will meet in this city to discuss the proposition which I submitted to it at Montreal in 1927 ; and this address must be regarded, therefore, as an introduction to a movement which one hopes will supply the necessary data, and so facilitate a working agreement between the two great mineral powers that alone have the avowed desire and the ability to ensure the peace of the world."

Coal and iron ore are the dominant minerals, as their products are necessary both in industry and war, and their exceptional abundance on the opposite sides of the North Atlantic has, according to Sir Thomas Holland, established the existing political supremacy of the United States and north-western Europe. The distribution of these minerals he considers so remarkable that he suggests its use as a further argument in favour of Wegener's hypothesis of continental drift. His main thesis is that America and the British Empire, owing to their control of coal and iron ore, can, if they will, stop war by refusing to supply the products of those minerals to any belligerent power. He claims that the only two nations that could fight for long on their own resources are the British Empire and the United States, and if they refuse mineral products to countries that infringe the Kellogg Pact, no war could last long.

This view agrees with Mr. Foster Bain's classification of minerals into three groups—those sold by the ton, such as coal and iron, the lack of which, he remarks, would put any country "under bonds to keep the peace" ; pound-minerals, such as copper and lead, which can be stored in sufficient quantity to last through an ordinary war ; and ounce-minerals, such as gold and platinum, which can be smuggled during war into any country which has sufficient credit to purchase them. Mr. Foster Bain holds that no nation could maintain a long war under modern conditions without native supplies of iron.

The power of the United States and the British Empire to stop war by refusing iron to the combatants would, however, be restricted by the enormous quantities held by all developed countries. The need for food might prevent a blockaded country beating its ploughshares into swords, but it could probably obtain enough iron for military purposes by turning its scrap into swords and its rails and railings into gun barrels and armour plate. The largest supplies of European coal are in Germany and Silesia, and most countries have unlimited quantities of material which could be used as iron ore if required in war, though it could not be profitably smelted at peace-time prices.

Sir Thomas Holland recognises that some instrument is necessary to enforce the recent treaties against war; and he believes that it could be found on the lines of the resolution submitted to the American Senate last February by Senator Capper, who proposed that the United States should refuse munitions to any nation that breaks the treaty for the renunciation of war. Sir Thomas Holland applauds that resolution, but proposes to modify its terms by substituting 'mineral products' for 'munitions'.

Sir Thomas Holland's second main proposition is that the political dominance of the North Atlantic countries is assured by the poverty in iron ore and coal of the lands west of the Pacific. The belief that the bulk of the world's supplies of coal and iron are beside the North Atlantic has been repeatedly expressed in America in recent years. This conclusion was advanced by Dr. C. K. Leith in 1925, and published in "Foreign Affairs" (New York, 1926), and it has been supported, after an elaborate inquiry, by Foster Bain and other American experts. According to Leith and Foster Bain, the notion that China is one of the richest countries in the world in coal and iron is fiction based on the reports by von Richthofen. Later estimates have reduced the supposed quantities of Chinese coal and ironstone. American authors have also thrown doubt on the reported numbers of the Chinese people and denied China's claim to have the largest population in the world. But the older figures have been supported by later evidence; and the same may happen regarding Chinese mineral resources.

The amount of coal and iron in China at present is utterly uncertain. The figures that were first put forward to replace von Richthofen's general statements were huge. Drake's estimate of the coal reserves of China was nearly 1,000,000 million tons; Inouye of Japan reduced the amount to 40,000 million tons. Dr. V. K. Ting, however, supports Drake's total as being "certainly of the right order of magnitude". The amount has been reduced to 23,000 million tons in the cautious calculations of the present Director of the Geological Survey of China, Dr. W. H. Wong, who naturally declines to include material in his returns without definite evidence. Further investigations may lead to the expansion of his figures, just as the British coal reserves have steadily grown, in spite of the heavy coal consumption, by the inclusion of previously unknown or incalculable reserves.

Some of the older statements as to the unlimited mineral wealth of China may have been due to Oriental exaggeration, and some recent estimates have been under-statements due to Western caution. The amount of coal in China is unquestionably enormous, and the western Pacific has far larger reserves of good iron ore than was recognised by some American estimates. Mr. Foster Bain, in a recent article, remarks that the supply of iron ores in Malaya and the East Indies is "truly great, running into hundreds of millions of tons". It is true as regards China that Tegengren in his memoir on the Chinese iron ores (1923–4) estimates the known or probable reserves as only 950 million tons; that amount is not so large as it looks, as the United States uses about 60 million tons a year. Nine-tenths of Tegengren's estimate consist of the ancient ores of Chihli and Fengtien; the remaining tenth includes 83 million tons of contact ores, which in most continents form a small proportion of the supply, and 5 million tons of other ore. There are in other parts of China large supplies of iron ore which were not included, as neither the quality nor quantity is known. The estimates of the iron ore supplies of China are as unreliable as those of Africa by Rösler (1921), who credited Africa with only one-sixth of the quantity known in Europe. That figure indicated lack of information rather than lack of African iron ore.

Sir Thomas Holland is no doubt correct in his conclusion that the Western Pacific will not disturb the political supremacy of the North Atlantic within any time of practical moment; but the predominance of the western world probably depends more on psychological factors than on the supplies of coal and iron ore. Sir Thomas Holland's address will arouse widespread interest, for it is illuminated by his gift of graphic phraseology, and its discussion will prepare for the consideration of this important problem at the Johannesburg meeting next summer of the Empire Mining and Metallurgical Congress.

Bateson and Mendelism.

Scientific Papers of William Bateson. Edited by R. C. Punnett. Vol. 1. Pp. viii + 452 + 7 plates. Vol. 2. Pp. viii + 503 + 29 plates. (Cambridge: At the University Press, 1928.) 42*s.* net each.

ACCORDING to a statement in his biography, recently published, Bateson intended at some time to write the history of Mendelism. Interesting as such a review would have been, the result has, in effect, been accomplished by the publication of his scientific papers and public addresses; for we have here not only a record of English work covering the early days of Mendelism, but also a general summary of much of the work done elsewhere. These papers, taken in conjunction with Bateson's biography, tell nearly the whole story of the fateful years following the rediscovery of Mendel's work in 1900. Possibly, in retrospect, emphasis might now be differently placed, and much of the detail relegated to the background, but the vividness of the recital by those in the midst of the enthusiasm of verifying and expanding Mendel's work might be lost in a strictly historical review.

When the history of Mendelism comes to be written, there can be little doubt but that Bateson's insistence on the importance of Mendel's work will receive its just appreciation. Both in Great Britain and in the United States, he did much to direct the attention of the younger generation to the new discovery. Even Bateson's controversies went far towards overcoming the inertia and scepticism of those who had adopted an attitude towards the study of heredity that was inimical to Mendel's clear-cut exposition. While Bateson's advocacy speeded up the study of heredity along Mendelian lines, we of the English-speaking race should not forget that the real discovery of the significance of Mendel's work came from Holland, Germany, and Austria, and that the discovery was not so much due to a literary find as to confirmation of Mendel's laws from data almost identical with his. It is, of course, a moot point whether, even then, these data would have received the scientific interpretation which Mendel furnished, had not the later work led to the recovery of his paper before the newer results were interpreted. The inside story of the finding of Mendel's paper has, I believe, never been told in print, which is a pity, since it is an extraordinary circumstance that three investigators should have simultaneously found a paper that had been completely forgotten for thirty-five years.

Bateson's study of discontinuous variability during the decade preceding 1900 had led him to the conviction that this sort of variability provides the most fruitful material for the study of evolution. In this connexion it is not uninteresting to follow Bateson's procedure in trying to find a solution of the kind of discontinuity present in serial homology and kindred morphological series. It is clear from his vague comparisons with ripple marks, etc., that he had not himself at that time (1890) become free from the kind of speculation familiar to the old morphology, despite his attacks on the methods in general of that school.

Comparing Bateson's paper read before the Royal Horticultural Society in 1899, when Mendel's work was unknown to him, with one read before the same Society in 1900, when he had de Vries's paper before him, it is apparent that while at the earlier date the importance of discontinuous variation, the study of single characters and of their inheritance, is emphasised, the underlying principles are not suggested. It is well to remember, however, that it took Mendel himself nearly ten years before he had in hand the experimental proof that established his laws.

The immediate extension of Mendel's principles we owe in part to Bateson and Punnett and the Cambridge School, but equally I think to Cuénot's series of brief but convincing contributions (1902–3), that not only established the application of the same principle to animals, but also furnished interpretations of several new principles. These came at a critical moment and served to widen the field of work. Bateson's interpretation of his own experiments on animals furnished equally important evidence of the extension of Mendelian principles to the animal kingdom.

It is to be regretted, I think, that the materials in the Reports to the Evolution Committee from the Cambridge School are not included in these two volumes (the summaries are, however, included), even had it been necessary to omit some of the other papers to make way for these. To the student of genetics the data given in these reports will be looked upon as the most outstanding contribution to genetics made during the earlier years of Mendelism.

A survey of Bateson's later work, after he had taken charge of the John Innes Horticultural Institution, cannot be attempted in a brief review. It expanded, and kept on expanding. Many of the new problems that arose were still unsolved at the time of his death, but the results of his inspiration and enthusiasm still continue. Sometimes I have thought that his delight in new adventures

distracted his attention from digging deep into the underlying principle of work already under way; yet, on the other hand, he pursued the evanescent 'rogues' to the very end, and 'sports' from root cuttings and 'chimæras' remained abiding problems.

Meanwhile work on the chromosome basis of heredity was coming more and more to the front, and its value in certain lines of research was everywhere becoming apparent. Bateson tried hard to give its proper due to this field of research, but it was only too apparent that it was distasteful to him and that he was, as he himself acknowledged, unfamiliar with first-hand information on cytology. He yielded for a moment after his last visit to America, but recanted, in part, in one of his latest papers. This has always been a source of regret to those of his friends 'over here' who had and have a high regard for his splendid abilities. An appreciation of the evidence and a little sympathy for these new lines of attack that were yielding promising results might, we thought, have simplified some of his perplexities.

From an early period Bateson's interest turned toward the study of variability in relation to species formation; and despite his sincere appreciation of the new openings presented by Mendel's discovery, he never succeeded in adjusting the results of the newer work on mutation and heredity to the historical problem of the evolution of species. He refused to minimise the importance of the older aspects of the problem, as many others have done, in the belief that after all they present a difficulty to those who insist on arbitrary definitions of species. Tradition had a powerful grasp on Bateson's mind, and he could not free himself from the supposed importance of some of the old difficulties connected with the origin of species. Systematists still follow their necessary methods of description, paying scant attention to genetic work; while geneticists are directing their main efforts towards solving other problems than the traditional problem of the infertility between species. Bateson stood firm in his contention that the outstanding question of genetics remains the species question.

The publication of these collected papers not only serves to perpetuate an important period in British biology, but also has made more accessible to students contributions that have been scattered in many journals, some of them difficult to obtain. The publisher and editor are to be congratulated on the accomplishment of a splendid memorial to an indomitable leader in the field of genetics.

T. H. MORGAN.

A Seventeenth Century Water-Bailiff's Duties and Rights.

A Description of the High Stream of Arundel, the Heads and Risings thereof; the Sundry Kinds of Fishes therein in their several Haunts; the Fishermen, and their Care and Service in preserving the Fish in Roading Time; the Swans and Eyries, and other Fowl in their several Limits; the Water Bailiff of the aforesaid High Stream in Arundel Rape, his Fees, Dues, and Duties. Edited, with Introduction, Notes, Map, and Index, by Joseph Fowler. (Extra Publication, No. 1.) Pp. 71. (Littlehampton: Nature and Archæology Circle, The Museum, 1929.) 7*s.* 6*d.*

IN this book we have a vast amount of antiquarian material that is of considerable local interest, and in so far as it touches on the rights and duties of a water-bailiff in mid-seventeenth century times, it will be of value to many whose interests lie beyond the bounds of West Sussex. Herein is printed in full a manuscript of which the first part is known only by two copies, which were made in 1899 for the Duke of Norfolk when defending his fishing rights, and the second part of which has been copied directly from the original. This was discovered after considerable search at Old Norfolk House, tied up with other manuscripts relating to wrecks upon the Sussex coast. The manuscript was known to Caraccieli (1766), Dallaway (1819), and Tierney (1834), but the first part of the original is still missing.

The river that we now know as the Arun is said to have been known of old as the High Stream in Arundell Rape, and in "middle times" as Alta Ripa; but by the Norman-English as Hault Rey. The water-bailiff who compiled the manuscript was one of considerable learning. He lived at Stopham, and his identity can only be conjectured, but the interesting suggestion is made that he may have been one of the Barttelott family. Apart from the fact that from the ancient style in which it is written, it is not always easy to understand what is exactly meant; it is replete with references to old customs, rights, and observances, and these are made increasingly valuable by the footnotes which have been made by the editor, which show a great amount of learning and research.

The natives of the county were called by the Saxons the Homelings, whilst those who came to dwell among them came to be known as the Comelings. With the modern popularity of Sussex, we fancy the Comelings are more in evidence than ever they were before. The author is sometimes severe

on the antiquarians who write without full knowledge or inquiry into the subject of their writings, and it must be admitted that if writers in other parts of the country could have access to documents such as that which has been printed, even supposing them to be in existence, antiquarian knowledge would be greatly increased.

In tracing the course of what we call the Arun from its sources, the author mentions the various streams and rivulets which feed the river, and gives concise information as to the bridges, and does not fail to say who should repair them and who has failed in this duty. An interesting tradition is mentioned that the river entered the sea in former times near Lancing, " where Bramber River (Adur) then likewise vented itself ". This is a subject that deserves further inquiry, for it is not inherently improbable. Such a course would take the river to the rear of Littlehampton, of which the common and many of the houses are situated on the old beach, and it would leave between the river and the sea the same eastward-extending spit of beach such as we find at the mouths of other rivers on the south coast. A somewhat similar case is seen at Seaford, where the ancient spit of beach, at one time known as the Bemblands, lay between the Ouse and the sea, when that river turned eastward from what is now Newhaven.

We should like to make many references to points contained in this old manuscript. There is a short description of the various kinds of fish that are found in the river, and a touch of affection shown for these creatures by the water-bailiff, who during the " fence-month ", or close season, finds it his duty to take them under his care. His duties were to preserve the swans, fowl, and fish, and to watch over the fishermen's " weares, weare-gates, weeles, shutting-nets and other engins whatsoever that may any way entrap or deceave the fish at that time ". He was to see that the meshes of nets were properly sized, and if the rods of the weirs were above the customary size " hee is then to cutt and deface them ".

The second of August is stated to be " swann-hooking or swann-hopping-day ". This is a variant of ' swan-upping ', which is said in the O.E.D. to be the true form of the word, that is, the taking up of the swans or cygnets for the purpose of marking them. The water-bailiff had to decide between the claimants of the cygnets of swans that had wandered from their rightful owners' waters, and to see that the swan-marking was properly carried out, also to claim his dues on such occasions. There is a list of the marks pertaining to the various persons of rank who had the right of keeping swans. In this we have the word ' butted ' frequently, and a note by N. F. Ticehurst that this refers to the pinioning of a wing " by the removal of the part of the wing distal to the carpal joint ". The swan-marks included besides butting on a wing, one or more notches on the beak, slits on the web of a foot, round holes on the web, the cutting off of one or both ' heels ' (hind-toes), cutting off a claw, the burning of initials on the beak, and various combinations and permutations of them.

The powers of the bailiff to prevent the catching of immature fish and the prevention of pollution of the stream were extensive, and it would be of interest to know if they are still maintained. Unaccustomed or unlawful instruments were not to be used, and if discovered they were to be defaced, or cut in pieces, or taken away or repressed. He was to see that there was " no shooting with gunns uppon their waters by reason whereof the swanns and fowle are frayed out of their haunts, and many times killed, especially by shooting at night ".

The extracts that have been made will show that the book is one which will appeal to all lovers of Nature, although the manuscript was not written for that purpose. It will be of considerable value to owners of fishing and other rights elsewhere, whilst to antiquarians it will be a book to linger over and handle with affection. The folding map is of great service in tracing the feeders of the Arun, and the bridges and other spots referred to in the text.

The Colloid Chemistry of Protoplasm.

The Colloid Chemistry of Protoplasm. By Prof. L. V. Heilbrunn. (*Protoplasma-Monographien*, Vol. 1.) Pp. viii + 356. (Berlin: Gebrüder Borntraeger, 1928.) 19 gold marks.

THIS first in a new series of monographs is written by one editor of the series, Prof. L. V. Heilbrunn, and dedicated to the other, Prof. Weber, who has taken an active part in editing the new journal *Protoplasma*. This journal has certainly been very successful as a channel of publication for the stream of experimental records, comment, and criticism which are the visible evidence that the study of protoplasm has been taken up from many new points of view, often only now possible as the result of advances in other sciences, especially chemistry and physics. It has yet to be shown, however, that the very fluid and

tentative generalisations in this field are ready to crystallise into monographs.

At the same time, the literature of this subject grows so rapidly, and has been so scattered, that a general presentation by one writer is very valuable. Fortunately, too, this literature is critically considered by Prof. Heilbrunn. Too often results are cited to-day without any consideration of the experimental technique by which they were obtained. As a result, a rational interpretation of protoplasmic processes is hindered as much by the effort to reconcile inaccurate and irrelevant data as by the experimental difficulties inherent in the subject.

The book is clearly, often even vividly, written, and the author lives up to his own advice: "We must cling to the facts which are broadly and generally true and leave the specific details to gods and encyclopædias." The author is more familiar with the zoological literature, but plants are by no means neglected. A constant attempt is made to link physical and chemical phenomena with morphological changes; this attitude is as valuable as it is rare.

Very few generalisations are probably yet ready for statement in this field. The most positive impression received from the perusal of the book is that the study of protoplasmic viscosity has proved a very fruitful line of attack. It will be a surprise to many biologists to read that the viscosity of protoplasm is often only a few times that of water. This conclusion must still be regarded as controversial, but the author seems to have a very strong case for his rejection of many figures which were more in accord with the prevalent impression of a very viscous 'slimy' substance. The changes in viscosity associated with the process of cell division are analysed. This association is now familiar to biologists, but morphology and colloid chemistry have still many joint problems in the phenomena of cell division.

There seems progress to report in the chapter upon the electric charge upon the protoplasm, where a clear distinction is drawn between the charge upon the surface layer and upon the colloid mass within the cell. When the action of acids and alkalis is considered, there seems little to show for much recent activity. Possibly the behaviour of iso-electric protein deserves more attention than it receives, as also the studies of Michaelis and others upon the permeability of protein-impregnated membranes in relation to hydrogen ion concentration. Certainly it is good to see attention directed to the lyotropic series when considering the action of salts. At one time Loeb's work upon the stoichiometric behaviour of proteins, with acids and bases, had thrust these phenomena too far into the background.

Many pages are given to a surface precipitation reaction, often exhibited by protoplasm when it escapes from the injured cell. Partly through its connexion with the presence of calcium, this reaction is brought into relation with the obscure phenomena of cytolysis and hæmolysis and with the clotting of blood. Cell division and vacuole phenomena are also considered mainly from the point of view raised in this tentative new interpretation of the surface precipitation reaction. The discussion is very stimulating and suggestive, but is of doubtful appropriateness in this monograph. Doubtless these chapters will appear in a more extended form, with full experimental protocol, in the pages of a journal like *Protoplasma*. We can only feel grateful that Prof. Heilbrunn has deferred the congenial task of detailed examination of these, as yet, mainly unpublished experiments long enough to permit the preparation of this more general monograph.

The botanist, by the way, will read with some surprise that "no one seems to have been especially interested in the process of vacuole formation" in the plant. Possibly the long controversy on the subject amongst French cytologists is regarded as too morphological in nature for consideration.

Our Bookshelf.

(1) *The Decline of the West.* By Oswald Spengler. Authorised translation with notes by Charles Francis Atkinson. Vol. 2: *Perspectives of World-History.* Pp. xi + 507 + xxxii. (London: George Allen and Unwin, Ltd., 1928.) 21*s.* net.

(2) *Kalki: or the Future of Civilisation.* By S. Radhakrishnan. (To-day and To-morrow Series.) Pp. 96. (London: Kegan Paul and Co., Ltd.; New York: E. P. Dutton and Co., 1929.) 2*s.* 6*d.* net.

(3) *Nomades: essai sur l'âme juive.* Par Kadmi-Cohen. Pp. xii + 221. (Paris: Félix Alcan, 1929.) 12 francs.

(1) THOSE who are closely engaged in scientific work are too preoccupied to worry about the future of civilisation. Most of them, if they consider the subject at all, assume that, with science in the ascendant, the future is secure. The books before us, however, take a different view, and raise many important questions. Spengler's theory is well known, namely, that civilisations have their periods of growth, maturity, and decay, and that our European type of culture has passed the summit. Whether or no the reader can accept everything that he finds here will make little difference to the

fascination that the book will exercise upon him. Whatever else he may or may not be, Spengler is never dull: his generalisations, his handling of facts—many of them as unfamiliar as they are interesting—his *aperçus*, make his pages almost as entrancing, at least for the moment, as Gibbon's. Not that he has Gibbon's greatness—perhaps his keen and lively glance is more like Voltaire's. Students of science should read Spengler, if only as a moral discipline; he will suggest to their minds some profound doubts.

(2) Mr. Radhakrishnan's little book is, of course, of a much more limited scope, but it repays reading. His thesis is the familiar one that our ethical and religious development has not kept pace with the spate of scientific knowledge which has engulfed us all. He questions the too commonly held assumption that mechanical technique is equivalent to civilisation.

(3) M. Kadmi-Cohen's book on the Jewish soul is relevant to the subject dealt with in the other two volumes, since it is concerned with the problem of spiritual leadership for Europe. He holds that, much as Europe already owes to the Semitic genius, the debt is not yet complete. J. C. H.

Primitive Beliefs in the North-East of Scotland. By the Rev. J. M. McPherson. Pp. xii + 310. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1929.) 12*s.* 6*d.* net.

IT is perhaps owing to the fact that north-east Scotland has been less well served by students that it does not figure so largely as the west in the literature of folklore and primitive belief. That this is not due to a lack of material is shown by the data which Mr. McPherson has collected and published in this book. As he points out, no systematic study of the folklore of this area has been made since the publication of "Notes on the Folklore of the North-East of Scotland", by Dr. Walter Gregor, nearly fifty years ago. Mr. McPherson has here collected and classified the large amount of material which has accumulated since that date, and in addition he himself has examined the ecclesiastical and burghal records which, while wishing to ignore superstitious practices, frequently were forced to note old ways and modes of thought and life in opposition to the views of the Church. Hence much valuable information upon such subjects as well-worship, tree, river and water spirits, fire festivals, and, above all, magic and witchcraft.

This latter subject claims a large share of the author's attention, and the whole of the second part of his book is devoted to the Black Art, which he examines exhaustively and in its various manifestations. It was in this area that some of the most famous of the Scottish witches were found—Isobel Goudie, for example. The actions of which they were accused were among the most primitive cited in all the witch trials. This is especially to be noted in connexion with fertility rites, in which both nudity and the use of urine are recorded. Control of the winds was a common prerogative of the witch, as might be expected in a country in which maritime activities play a large part. Belief in this ability continued until well into the nineteenth century. Although it has been possible to indicate only one or two points of interest in Mr. McPherson's collection, his book is a store of information on every side of old Scottish custom and belief.

Morphologie und Physiologie des Formwechsels der Moose auf genetischer Grundlage, II. (Untersuchungen, ausgeführt mit Unterstützung der Notgemeinschaft der deutschen Wissenschaft zu Berlin und der Gesellschaft der Wissenschaften zu Göttingen.) Von Fritz von Wettstein. (*Bibliotheca Genetica*, herausgegeben von Prof. Dr. E. Baur, Band 10.) Pp. iii + 216 + 10 Tafeln. (Leipzig: Gebrüder Borntraeger, 1928.) 48 gold marks.

THIS is the second part of Fritz von Wettstein's well-known experimental work on mosses, the first part having appeared in 1924. The present contribution deals largely with hybridisation between different species and genera of mosses, and with heteroploidy produced experimentally by Marchal's original method of wounding the sporophyte. By regeneration from a hybrid sporophyte, and subsequent hybridisation again, various unbalanced types can be obtained, in which the chromosomes may be regular multiples, but more sets will have been derived from one parent species than from the other. These are spoken of as heterogenomatic, homogenomatic forms being those derived from wounding successive generations of sporophytes in pure species, or from crosses giving a balance of chromosome sets. In a section on cell-size, a law for the increase of size accompanying various degrees and kinds of polyploidy is worked out.

Extensive comparative studies of the leaves, paraphyses, sex organs, capsules, stomata and cells in all the various kinds of polyploid hybrids form a basis for the analysis of the genetic effects of each chromosome set. This work has become sufficiently extensive to have wide bearings on various fundamental genetical problems; and mosses, in their structure and life-history, possess certain advantages which are not shared by flowering plants. R. R. G.

Handbuch der Vererbungswissenschaft. Herausgegeben von E. Baur und M. Hartmann. Band 1: *Die cytologischen Grundlagen der Vererbung.* Von Karl Bělař. Pp. iv + 412 + 2 Tafeln. (Berlin: Gebrüder Borntraeger, 1928.) 80 gold marks.

WHILE the volume under notice is mainly devoted to the animal side of the cytological basis of inheritance, there is also a considerable amount of well-chosen evidence from plant material. Much of the evidence presented can be found in such works as Wilson's "Cell", but some of the recent developments have been more fully considered.

The earlier chapters deal with such topics as cytomorphology, cell and nuclear division, cell differentiation, fertilisation and parthenogenesis. In later chapters, considerable space is devoted to problems relating to chromosome reduction, individuality of the chromosomes, and the relation of

the chromosomes to heredity. The last chapter asks the question whether formed cytoplasmic bodies such as mitochondria are bearers of hereditary characters, and, after considering the evidence almost entirely from the animal side, leaves the answer an open one.

References are made to the author's own experimental work on mitosis. Considerable space is taken up with a summary of recent developments in the genetics of *Drosophila*, and an account is also given of Wettstein's work on the production of polyploid mosses. The book will prove useful to those who wish to keep abreast with recent developments in this field.

Les méthodes nouvelles en analyse quantique (mécanique quantique, mécanique ondulatoire). Par Dr. Julien Pacotte. Pp. viii + 139. (Paris : Albert Blanchard, 1929.) 22 francs.

THE object of this book is to give an account, from as many different aspects as possible, of the new methods in quantum mechanics. The first part, based on papers published before July 1926, contains six chapters. These deal with general quantum principles, Heisenberg's matrix mechanics and Dirac's numbers, de Broglie's waves, Schrödinger's wave mechanics, perturbations, and applications. The second part contains two chapters, which link up the new quantum mechanics with relativity and statistical mechanics.

The author's style makes the book easy and pleasant reading. He takes great care to point out that the different conceptions are not so much different theories as different aspects of the same theory. It is shown that Heisenberg's matrices suggest Schrödinger's work, and conversely. Perhaps some readers will consider that the space devoted to applications is too small. This section deals only with the harmonic oscillator and the hydrogen atom. At present the most successful parts of the new theory seem to be its applications, whereas the theoretical foundations are not as yet very secure, and have even been described as " a dodge, but a very good dodge ".

H. T. H. P.

Fitness for Work. By Prof. T. H. Pear. Pp. 187. (London : University of London Press, Ltd., 1928.) 5*s*. net.

PROF. PEAR has in this little book made an interesting study of fitness for work. He rightly remarks that far more books are written about unfitness. He analyses the aspects of successful achievement which force us to attribute to a worker capacities, abilities, or skills, and then the motives that lead a person to select, continue in, or change a particular work, and finally discusses some current conceptions of the function of work. Stupidity and laziness would almost seem to be out of place in a study of fitness, but the author presents some novel and provocative remarks on the two and shows their relation to such a theme. The final chapter on the question of the value of industrial skill opens up some very vital problems of modern industry. Two apparently opposite tendencies are clearly visible in the modern State : on one hand, there is an undoubted increase in the application of mechanism, with a corresponding diminution in the need for personal skill, but on the other, the very mechanism itself demands more people to adapt and adjust it, that is, to deal intelligently with mechanism, and modern organisations demand still greater skill on the part of those in authority.

Prof. Pear's book should appeal to a wide range of readers : his style is easy and not technical, so while the psychologist will find much to interest him, the general reader will find no terminological difficulty.

Kurzes Lehrbuch der Chemie in Natur und Wirtschaft. Von Prof. Carl Oppenheimer und Prof. Johann Matula. Zweite neubearbeitete Auflage. Band 1 : *Allgemeine Chemie*, von Prof. Johann Matula ; *Anorganische Chemie*, von Prof. Carl Oppenheimer. Pp. xiv + 566. 23 gold marks. Band 2 : *Organische Chemie*, von Prof. Carl Oppenheimer. Pp. xiv + 471. 19 gold marks. (Leipzig : Georg Thieme, 1928.)

THE authors have accomplished the considerable feat of giving a comprehensive delineation of present-day chemistry within the limits of little more than a thousand pages. The account is well proportioned and up-to-date. Particular emphasis has been laid upon the underlying principles of the science, and upon its relationships to biology and technology. The introductory section of 258 pages by Prof. Matula forms an admirable preparation for the succeeding systematic treatment of inorganic (pp. 294) and organic (pp. 453) chemistry by Prof. Oppenheimer. The work offers at a reasonable price a useful German text for advanced students, teachers, biological chemists, and all who are interested in the industrial applications of chemistry.

Matter, Electricity, Energy : the Principles of Modern Atomistics and Experimental Results of Atomic Investigation. By Prof. Walter Gerlach. Translated from the second German edition by Dr. Francis J. Fuchs. Pp. xii + 427. (London : Chapman and Hall, Ltd., 1928.) 30*s*. net.

THIS volume covers a wider field than is usual in a short treatise on atomic physics, and touches upon most of the important work done between about 1910 and 1926. It includes sections on atomic rays, superconductivity, conduction in crystals, spectrophotometry, and electrically and optically controlled chemical reactions, in addition to the more usual topics, and if it were well translated, would be invaluable both as an advanced text-book for honours classes in physics, and as a survey of the subject for research workers in other branches of experimental science. Dr. Fuchs has, however, failed to do justice to the original, and his translation can only be recommended as it stands with the warning that the reader must be prepared to be irritated by the many unusual expressions that he employs.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Total Solar Eclipse at Iloilo on May 9.

THE following is a preliminary note on the results of the eclipse expedition of Dr. K. H. Hartline, Mr. W. E. B. Lloyd, and myself. The preparations for the expedition were made at Johns Hopkins University, Baltimore, and were as complete and permanent as possible to reduce to the minimum the work that remained to be done in the eclipse camp. This was necessary owing to the fact that Dr. Hartline was unable actually to make the journey, and Mr. Lloyd and myself had only twelve days in which to put up the apparatus.

Our site was near Iloilo in the Philippines, in the grounds of the Normal School of La Paz, about a mile and a half north of the U.S. Naval Observatory party. Totality lasted 3 min. 42 sec.; but throughout, the sun was covered by a veil of high cirrus.

Ten panchromatic plates (H. & D. 2000, Imperial Dry Plate Company) were given exposures ranging from one to forty seconds with a 5-inch visual Alvan Clarke lens of 6-foot focus through a green Ilford 'Beta' filter transmitting λ4450-λ6950. The focus is good and the shorter exposures show much inner coronal detail. Longer exposures bring up streaky cirrus which confounds coronal detail; yet on these one can trace one streamer to three solar diameters from the limb.

Our intention was, if fine, to get extreme coronal extension by the use of these very rapid plates and the filter which would diminish the scattering of the light. In that the very considerable cloud veil thwarted us; but we feel that, under the conditions obtaining, had it not been for our filter, we should almost certainly have got the inner corona only.

Using a neo-cyanin dyed plate and an infra-red filter, we gave a single exposure of about 200 sec. with a 3-inch rapid rectilinear lens of 24 inches focus (*F* 8). This plate-filter combination was sensitive between about λ7000 and λ9000 with a maximum at λ8500. On this plate the corona is completely confined to within half a diameter of the sun from its limb, is extremely intense—practically 'burnt out'—and has a very abrupt edge. We believe this effect to be far too marked to be attributed entirely to the steep intensity gradient of the photographic combination; but it will be necessary to decide this point on returning by measuring the plates with a micro-photometer, etc. Should the effect prove to be real, it will confirm the view that the light of the outer corona is entirely sunlight scattered by particles very small in comparison with the wave-length of light.

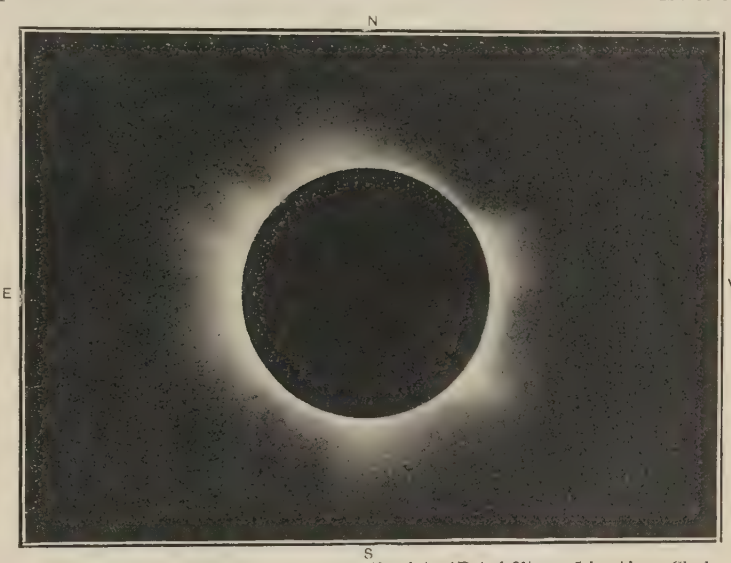

FIG. 1.—One second exposure. Panchromatic plate, 'Beta' filter. 5-in. Alvan Clarke lens, 6-ft. focus.

FIG. 2.—Two seconds exposure. Panchromatic plate, 'Beta' filter. 5-in. Alvan Clarke lens, 6-ft. focus.

Another effect on this plate which will also require confirmation by measurement, etc., is an apparent filling-in on the infra-red plate of what on the panchromatic plates are wedge-shaped gaps in the corona extending in towards the limb. If this effect turns out to be real, it would suggest intervening screens of particles large enough to blot out visual rays but small enough to transmit those of the near infra-red.

Lastly, this infra-red plate is the only one on which no cloud appears; it has completely penetrated—or rather *ignored*—the intervening cirrus.

The cloud badly interfered with our attempt at infra-red spectroscopy—for which the *quantity* of

light was all-important. In this a similar neo-cyanin plate was used with infra-red filter in conjunction with a concave objective grating (kindly lent by Prof. R. W. Wood), $2\frac{1}{2}$ in. × $3\frac{1}{2}$ in. aperture, 15,000 lines per inch and about 5-foot focus. On each of the two flash spectra obtained, only four emission arcs appear, three of which are the infra-red calcium triplet in the region around λ8500-λ8600. Unfortunately, owing to a displacement of the whole spectrum along the line of dispersion, due to a warping by the heat of the wooden tube and finder, the focus is poor. The fact, however, that these arcs appear at all under the conditions of the sky prevailing is hopeful for the use of these plates in the photography of the near infra-red during an eclipse, provided one has a clear sky.

In addition, two fairly successful colour pictures were made of the corona with the new Du Fay colour process film (kindly supplied by the Imperial Dry Plate Company).

Penetration of Rocks by Electromagnetic Waves.

DURING the month of June, research work has been carried out at the Mammoth Cave, Kentucky, under the joint auspices of the United States Bureau of Mines and the Geological Survey of Canada, by permission of both of which this communication is being published. The disputed question of the extent to which wireless waves will penetrate into the earth has a high scientific interest, and it bears directly on some practical modern methods of geophysical prospecting for underground conductors such as the sulphides of lead, iron, and copper.

Previous investigations have been made at the Bureau of Mines' Pittsburgh coal mine, in the Caribou Mine, Colorado, and in the Mount Royal Tunnel, Montreal. An account of the experiments may be found in *Technical Paper* 434, pp. 37-40, Bureau of Mines, Department of Commerce, Washington, D.C., and in the *Proceedings* of the Institute of Radio Engineers, Vol. 17, No. 2, Feb. 1929. References to the subject have also appeared in the columns of NATURE. All this work has been of a dubious character because of the presence of iron pipes and rails, and of copper conductors connected with electric lighting. There were three schools of thought; some claimed that the radiations came through the entrance, others that the waves passed through the rock, while the remainder considered that the effects were transmitted along wires, pipes, and rails. Probably all three paths are available, but certainly the Mount Royal experiments proved beyond question that the short waves of length 40 metres (7500 kilocycles) failed to enter the tunnel by any of these means for more than a few hundred feet. Longer waves, broadcasting upwards, were heard and measured throughout the entire three and a half miles of tunnel.

To settle the question, Mammoth Cave, Kentucky, was selected for experiments and it proved a fortunate choice. This cave has not been electrified for illumination, and the managers were good enough to remove telephone wires. There are no conductors whatever in the cave except here and there short lengths of iron hand rails. The exits are filled by and sealed with the waters of Echo River and the River Styx, which flow into Green River. A few years ago a new entrance was found and some electric wiring introduced; this is four miles away overland and eight miles away by cave. A careful survey was made both under and above ground so that corresponding points could be located and levels known. Most of the work was carried out above River Hall, with 300 feet of overburden, about 200 feet of Mammoth Cave limestone, capped by 100 feet of Cypress sandstone. The resistivities of these rocks *in situ* were ascertained by electrical prospecting to be of the order of 10,000-20,000 ohm-cm.

Broadcasting Wave-length.—The words and music from Louisville, Nashville, Cincinnati, were received on a No. 26 Portable Radiola superheterodyne six-tube set, and the bearing was taken with the small loop which is part of the apparatus. These signals were traced into the cave from the entrance and were lost at 500 ft. from the mouth, where the overburden is 150 ft. Yet under the Mammoth Dome, 1000 ft. in the cave, capped by an ascertained thickness of 75 ft., mostly sandstone, the signals were clear enough, and these were traced along a rather narrow tunnel for 300 ft., when the thickness was 150 ft.

On a later occasion, Messrs. Joyce, Barlow, and Kidd took a three-hundred-foot aerial and gave three turns of it round the loop, so as to form a close coupling, and led the other end to the ground. In this manner there was at night good audible broadcasting in River Hall 300 ft. below the ground and more than a thousand feet from the entrance, at a point approached by the famous tortuous passage well named the Corkscrew. Next night, signals and speech were also audible at Echo River, reputed to be 350 ft. underground. The conclusion is irresistible that waves from distant stations can be detected under 300 ft. of sandstone and limestone, waves which do not come through the entrance, and do not pass along conductors.

Long-wave Stations.—Code signals from about six stations (Long Island and others ?) were heard on a loop with a Model RE low-frequency receiving equipment, consisting of an antenna coupling unit, a radio frequency amplifier, a low-frequency receiver, and a tuned audio amplifier. These signals were clear enough to hear, but their intensities were hard to measure, partly owing to static. The wave-fronts appeared to be mainly vertical, and the waves must therefore have been travelling through rock rather than down from above. The reception was again at River Hall, 300 ft. below the surface plateau near the camping ground of the Mammoth Cave Hotel. The bearings of these signals obtained above and below ground were nearly identical. This picture of a wave, with its front mainly vertical, travelling through the rock, just as through the air, is rather novel. We could pick up these unidentified stations with three turns of wire on a four-foot-square frame, and we obtained bearings therewith.

Horizontal Wave Fronts.—A circular horizontal transmitting loop, 100 ft. in diameter, was placed on the ground, and the insulated wire could be tapped so as to give one to ten turns as required. A rectangular receiving coil of three turns 40 × 10 sq. ft. was placed on the floor of the cave at River Hall (300 ft. down). Currents of known magnitude of about half an ampere were introduced into a single turn of the loop, using a gasoline engine generator to excite an oscillator. The high-frequency loop current was modulated by applying a 500-cycle alternating current potential on the oscillator plates. The frequency was varied by steps of ten, from 20 to 110 kilocycles. The received voltage on the coil was measured in microvolts, and averaged about four, suggesting a flux of 10^{-9} lines per sq. cm. in the cave, due to half an ampere in the loop above ground. It was a most remarkable fact that the 20 and 30 kilocycle frequencies boomed out loudly compared with the 40-100 kilocycle frequencies. Measurements made above ground on the same frequencies

showed no such emphasis, and there is a strong suggestion that these frequencies (20-30 kc.) pass with markedly less absorption through the rock. This question must stand over for a fuller investigation. The selectivity did not appear to be a function of the receiving instrument.

Audio Frequencies.—When 500-cycle frequency alternating current was impressed on the full ten turns of the 100-foot diameter circular loop, powerful signals were received with headphones both with and without a three-stage amplifier, using a 400 turn 3×2 sq. ft. rectangular coil, at depths of 100 ft. and of 300 ft. Of particular interest is the fact that detection was readily made without amplifier, in the Mammoth Dome, 900 ft. on an inclined line from the horizontal loop. We conclude that the electromagnetic effects of a 500-cycle frequency passed through 900 ft. of continuous rock. It is intended to publish a full report on these experiments in due course.

New Determination of the Curvature Radius of Space-time.

As communicated in a cablegram of April 10 (NATURE, April 20, p. 618), my statistical formula, concerning any two groups of stars 1, 2,

$$R^2 = \frac{c^2[\overline{(rv_r/v)_1}^2 - \overline{(rv_r/v)_2}^2]}{\overline{v_1}^2 - \overline{v_2}^2},$$

which is fully derived in a monograph on "The Size of the Universe", shortly to be issued by the Clarendon Press, Oxford, when applied to 29 Cepheids observed by R. E. Wilson of Albany, yielded for the radius R of de Sitterian space-time the value $3{\cdot}0 \times 10^{11}$; when applied to 35 stars of the *O*-type observed by J. S. Plaskett of Victoria, gave $R = 3{\cdot}2 \times 10^{11}$; and when applied to 246 stars taken from Young and Harper's list, $R = 3{\cdot}4 \times 10^{11}$ astronomical units. The latter batch of objects consisted of those of R. K. Young and W. Harper's "1105 Stars" (*Publ.* Domin. Astrophys. Observatory, Victoria, B.C., vol. 3, No. 1, Ottawa, 1924) numbered 500 to 1105, the distances of which, r, equal or exceed 50 parsecs, and the radial velocities of which are less than 100 km./sec. In the formula just quoted, c is the velocity of light, v_r the radial and v the resultant velocity, relative to the sun. (It may be noticed that in Young and Harper's memoir the radial velocities are corrected for the solar motion, but Prof. Young was kind enough to send me a complete list of the original velocities reduced, as usual, to the sun.)

Since the coincidence of these three R-values has seemed very encouraging, I have recently returned to the complete list of Young and Harper's stars, taking in also all those numbered 1 to 499, and, again, satisfying the conditions $r \geqq 50$ parsecs, $v < 100$ km./sec. This gave in all 460 stars, for which all data (r, v_r, μ, and therefore v_t and v) are available. Having divided this material into two groups of 230 stars each, ranging from $r = 50$ to 100 and from 100 to 1000 parsecs, and applied to these the above formula, I had the satisfaction of finding the said R-values corroborated excellently. In fact, the laborious computation, completed on July 11, gave for the nearer sub-group

$$\overline{s_1}^2 = \overline{(rv_r/v)_1}^2 = 2109 \text{ parsec}^2, \quad \overline{v_1}^2 = 1754 \text{ km.}^2/\text{sec.}^2,$$

and for the more distant one

$$s_2{}^2 = 16{,}930, \quad \overline{v_2}^2 = 2185,$$

where s_1, s_2 are, by the way, the actual distances of the several stars from their perihelia. Now, these values, substituted into my formula, give

$$R = 1{\cdot}76 \times 10^6 \text{ parsecs},$$

or $3\ 63 \times 10^{11}$ astronomical units, or 5·74 million light years, in excellent agreement with the Cepheid and the *O*-stars results. In view of the numbers of the last group (460 stars), the latter value has by far the greater weight, and can be accepted with confidence, at least to two figures, as the actual value of the space-radius.

The complete list of data for the $29 + 35 + 460$ celestial objects will be found in "The Size of the Universe", now in proof, and a good number of details will be given sooner, in a paper announced for the next meeting (Aug. 26–29) of the American Astronomical Society at Ottawa.

Here it may still be added that the greatest possible distance apart of two points in elliptic (polar) space is $\frac{1}{2}\pi R$, and thus *nine million* light-years. In view of this, distances such as 140 million light years attributed by Shapley and Hubble to a group of fainter spiral nebulæ are entirely out of the question and (since my radius is stoutly supported by several hundred stars of a variety of kinds) must be subjected to a thorough revision. It seems that even the distances of the Magellanic Clouds, or at least that of the greater one, which of late served as a yardstick for several estimates, has been exaggerated. In fact, in a letter of Feb. 11, 1929, Prof. Shapley, kindly answering a number of my questions, says that the distances of the globular clusters are now being revised, and warns me that "the Large Magellanic Cloud will probably move in considerably when the present study of magnitudes and variable stars is completed". The latter warning was particularly agreeable to me, since I had just at that time derived the Cepheid value 3×10^{11}, which was some 15 times smaller than that obtained from the Magellanic Clouds (in conjunction with the clusters) in 1924. One can now confidently expect that when these objects, Clouds, and all "move in considerably closer, they will also confirm the radius of the order of 3×10^{11} a.u.".

I do not hesitate at any rate to assert that there are, in our world, no distances exceeding nine million light years, so that the present placing of Virgo (140 million) is utterly inadmissible.

The total volume of space being $\pi^2 R^3 = 54 \times 10^{18}$ cubic parsecs, there is ample room for some millions (but not 10^{16}, as Hubble imagines) galaxies comparable in size with our own Milky Way.

The Possibility of Observing an Emission Spectrum of the Calcium Substratum in the Galaxy.

IN a very interesting paper, "Physical Properties of a Gaseous Substratum in the Galaxy" (*Astrophys. Jour.*, **69**, p. 7; 1929), Gerasimovič and Struve have recently given strong evidence of a uniform gaseous medium of calcium in interstellar space. The absorption coefficient per parsec for the interstellar K line was found by them to be $3{\cdot}4 \times 10^{-4}$. If such a general calcium substratum exists, the question may arise: Is the density of this substratum strong enough to allow the emission spectrum of the Ca^+ atoms to be expected in the spectrum of the night sky?

The mechanism by which the emission spectrum would be produced must be analogous to that giving the spectra of diffuse nebulæ. We have thus two

kinds of emission, partly resonance radiation or line absorption with subsequent emission by steps and partly photoelectric ionisation with subsequent recombinations. In the nebulæ the second mechanism is much more powerful than the first one (compare Zanstra, *Astrophys. Jour.*, **65**, p. 50; 1927), but in interstellar space the two mechanisms take about the same active part in producing the emission spectrum of the Ca^+ atoms.

To begin with the resonance radiation, for example, the K line, the problem of finding the energy density of the interstellar K line on our point in space is, when rigorously treated, rather difficult and leads to a complicated integral equation. The problem is, however, in several respects analogous to that of finding the energy density inside a star. Let us first consider a stellar system embedded in a calcium atmosphere of high density, or in other words, we consider the case when the absorption coefficient for the K line is much greater than $1/R$, R being the radius of the stellar system. As is obvious, the density of the interstellar K line must then be considerable, because the K frequency radiation emitted by the stars must work its way out from the stellar system. The absorption coefficient found by Struve and Gerasimovič is, however, of the same order of magnitude as $1/R$, and, as will be shown in the following, the interstellar K resonance line is not strong enough to be expected in the spectrum of the night sky.

For purposes of simplification, we will consider a stellar system of spherical shape with a radius of 5000 parsecs and with the sun in the centre. Further, we assume both the density of the interstellar starlight E_s and the density of the interstellar K frequency radiation E_k to be constant within the stellar system. The last assumptions are of course not justified if the radius of the stellar system is much greater than $1/\kappa$, where κ is the absorption coefficient, but in our case the assumptions will give a maximum value of the energy density of the interstellar K resonance line in the centre not very far from the truth. Supposing every K line absorption to be followed by K line emission, we derive easily the following expression:

$$E_k/E_s = e^{\kappa R} - 1.$$

With $R = 5000$ parsecs we find $E_k/E_s = 4{\cdot}5$. The energy density of the interstellar K line would accordingly be about 4·5 times stronger than the energy density of the integrated starlight of the same wavelength. Remembering, however, that most of the stars have a strong K absorption line, that the width of the interstellar K line is only about 0·3 A. (Struve and Gerasimovič, *loc. cit.*), and that only 30 per cent of the light from the night sky is due to the stars (Dufay, *Bull. de L'Observatoire de Lyon*, **10**, 9; 1928), we must admit the chances of finding the K resonance line in the faint spectrum of the night sky to be very small. The spectrum of the night sky has been carefully investigated by Dufay, who has kindly communicated to me that the image of the slit on the spectrum plates was never less than 0·04 mm. The dispersion was about 120 A. per mm., that is to say, the interstellar K line would in Dufay's spectrograph be diminished 16 times in comparison with the continuous spectrum of the starlight or 53 times in comparison with the continuous spectrum of the night sky. If there had been no K absorption line in the spectrum of the night sky, the interstellar K line would be superposed on the continuous spectrum and just strong enough to be detected, or about 0·1 magnitude stronger than the continuous spectrum. As, however, the K line is very strong in absorption in the spectrum of the night sky, there is no possibility of detecting the interstellar K emission line.

In the foregoing we assumed every K line absorption in space to be followed by K line emission. This is, of course, not true, as many of the quanta are split up into the diffuse doublet $1\delta - 1\pi$ and the forbidden transitions $1\sigma - 1\delta$. As to the latter doublet, the chances of detecting it in the spectrum of the night sky are, however, rather good. This doublet is not present in absorption in stellar spectra, and the interstellar absorption lines in the spectrum of the integrated starlight are, as is easily shown, more than filled by the resonance lines. As the forbidden doublet (λ7293·43 and λ7325·91) arises both by resonance and by emission by steps, the lines seem to be strong enough to be detected superposed on the continuous spectrum of the night sky. It may, however, be rather difficult to photograph the red part of the faint spectrum of the night sky, but it seems possible, and it would be of considerable interest if such an investigation were carried out.

As was mentioned above, an emission spectrum of the Ca^+ atoms may also arise by electron captures of Ca^{++} atoms. To get an idea of the strength of this process compared with the resonance radiation, I made a calculation for the K line with the following assumptions. The absorption coefficient at the head of the series was equalised with the absorption coefficient of the K line and was supposed to decrease as $1/\nu^2$ (Milne, *Phil. Mag.*, **47**, p. 209; 1924). Further, one capture out of ten was assumed to give rise to the K line. With the temperature and dilution factor for the integrated starlight beyond the series limit given by Struve and Gerasimovič, I found the intensity of the interstellar K line just equal to the intensity of the continuous spectrum of the starlight which corresponds to the temperature 7000° and the dilution factor $5{\cdot}5 \times 10^{-15}$. This mechanism of radiation seems thus to be of about the same power as the resonance radiation.

As a summary of the above, we may propose the forbidden doublet $1\sigma - 1\delta$ to be present in emission in the spectrum of the night sky. The H and K emission lines are, on the other hand, not to be expected. As to an eventual emission spectrum of Ca^{++} atoms, it seems not possible at the present time to make any statement. If emission lines due to interstellar calcium could be found in the spectrum of the night sky, they would give valuable information on the density of the calcium substratum and the size of the galactic system.

The Relative Masses of the Proton, Electron, and Helium Nucleus.

THEORETICAL considerations suggest that the square root of mass may be more interesting and important than mass itself in the case of the ultimate particles of matter. For in the modern theory of matter, electric charge is more fundamental than mass, and the dimensional formula for electric charge e is $M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-1}$ in the electrostatic system. Thus e is proportional to $M^{\frac{1}{2}}$. This appears in more definite form if we adopt the classical point of view that the mass of the ultimate particles is entirely of electromagnetic origin. According to the theory of relativity, energy and mass are related by the well-known equation $E = mc^2$. But if the energy E is entirely electromagnetic, $E = \int \frac{1}{8\pi}(F^2 + H^2)dv$, where F and H are the electric and magnetic field intensities respectively. Thus m depends on the square of F and H, corresponding to the fact that it depends on the

square of e. Carrying out this process yields the well-known formula

$$m = k\frac{e^2}{ac^2},$$

where m is the mass of a particle of charge e and radius a. The numerical quantity k (usually given as $\frac{2}{3}$) depends on the particular assumptions made concerning the distribution of charge. This idea of the importance of the square root of mass is of interest, we believe, in connexion with the following facts concerning the relative masses of the proton, electron, and helium nucleus.

If m and M are the masses of the electron and proton respectively, then $\rho = M/m$ is a pure number. Furthermore, on the basis of quantum theory one might expect a dimensionless quantity of such a fundamental character to possess integral properties, that is, it would be an integer, half integer, or the square of an integer, etc.

The value of ρ according to the "International Critical Tables" and the "Handbuch der Physik" (vol. 22, p. 81) is 1847. Birge, however, in a paper on the probable values of the general physical constants (to be published in the *Physical Review* Supplement) gives two values of $(\rho + 1)$, one $(\rho_1 + 1)$ obtained from spectroscopic data, and the other $(\rho_2 + 1)$ from the value of e/m from the deflection experiments with cathode rays. The corresponding values of ρ are:

$$\rho_1 = 1838 \pm 1.$$
$$\rho_2 = 1847 \pm 2.$$

(The opinion has been expressed that ρ_1 and ρ_2 may be really different quantities.)

It is interesting to note that

$$\sqrt{\rho_2} = 42{\cdot}98.$$

This suggests that possibly

$$\rho = 43^2 = 1849, \quad . \quad . \quad . \quad (1)$$

a value which is within the limits of error of ρ_2.

At first sight, 43 seems to possess no distinctive characteristics to qualify it for such an important position in the domain of atomic physics. But

$$43 = 1^2 + 2^2 + 2^2 + 3^2 + 3^2 + 4^2.$$

If we multiply the numbers on the right of the equality by two, we obtain the well-known sequence,

$$2, \quad 8, \quad 8, \quad 18, \quad 18, \quad 32,$$

giving the lengths of the successive periods of the periodic table of the elements. This numerical relationship can be stated in terms of physics in the following words. The number 43 is half the atomic number of the inert gas of highest atomic number, namely, radium emanation.

It is, of course, impossible at the present time to say whether the integral relationship (1) is either exact or significant. But if it should turn out not to be exact, it might nevertheless be significant. The latter point is illustrated by the fact that the integral relationships between the atomic masses as determined by Aston and others are only approximate.

The helium nucleus is usually regarded not as an ultimate particle of matter, but as a structure of four protons and two electrons. Since the latter conception lacks experimental demonstration, it is not certain that it is correct. Perhaps the helium nucleus should be regarded as an ultimate particle just as the proton and electron. The facts seem to indicate that in some sense of the word the helium nucleus is at least 'more nearly ultimate' than the nuclei of the atoms of atomic number greater than two. In the first place, the alpha particle is the only positive particle emitted in naturally occurring radioactivity. Secondly, the experimental data as usually interpreted indicate that the alpha particle is the chief constituent of the nuclei of atomic number greater than two. Furthermore, the packing fractions demonstrate that, if helium is composed of four protons and two electrons, it is an extremely stable combination. Possibly this indicates that in the process of combination the protons and electrons have entirely or almost entirely lost their identity. This latter idea represents a fusion of the usual conception of the helium nucleus and the conception that it is an ultimate particle. (It is of course not impossible or improbable that in all nuclei the component particles have lost their identity.)

Let M_{He} and M be the masses of the helium nucleus and the proton respectively. If the helium nucleus is regarded as an ultimate particle, one might expect M_{He}/M to be the square of an integer just as ρ is. As a matter of fact, $M_{He}/M = \sim 2^2$.

This relationship can be formulated more precisely as follows. If m_H and m_{He} are the masses of the hydrogen and helium atoms respectively, then

$$\frac{m_{He}}{m_H} = \left(\frac{Z_{He}}{Z_H}\right)^2 \cdot \frac{1}{1+\alpha}, \quad . \quad . \quad (2)$$

where Z_H and Z_{He} are the atomic numbers of hydrogen and helium respectively, and α is the fine structure constant. Part of this relationship was pointed out by A. C. Lunn (*Phys. Rev.*, **20**, 1; 1922) before Aston's recent data were available. The value of α computed from Aston's data (*Proc. Roy. Soc.*, **115**, 510; 1927) by equation (2) is $0{\cdot}00724 \pm 25 \times 10^{-5}$, in excellent agreement with the spectroscopic value 0·00729.

In the quantum theory of the electron the mass enters as an arbitrary constant. Perhaps the facts presented here will be of value in constructing a better theory of the proton and electron, which will account for their masses, or at least their relative masses.

Chromosome Numbers in the Agropyrons.

THE taxonomy of the Agropyrons is in a very unsatisfactory condition, and authorities differ widely in their classification of this genus. This undoubtedly is owing to the wide range of variability existing within the so-called species and also to the large number of intergrading types that occur between these species. The difficulty of classification extends to the seeds; analysts and seed merchants are unable to separate the desirable and undesirable forms with reasonable accuracy.

Since this genus contains a number of native and introduced hay grasses which are particularly well adapted to conditions in western Canada, it is a matter of considerable importance to clear up the foregoing difficulties. It was felt that a cytological study might assist greatly in overcoming some of the taxonomic problems and provide a valuable guide to plant-breeding work.

The plants examined were grown in the greenhouse during the winter of 1928–29. Artificial lighting for a part of the night enabled the work to be carried on in the winter months. Slides were prepared both from pollen mother cells and from root tips. Pollen mother cells proved to be more suitable, and most of the counts were taken from this material. The proper stage was quickly ascertained by Belling's aceto-carmine method. The florets were fixed in Carnoy's 6-3-1 solution for two minutes and then for

twenty-four hours in Zenker's fluid. They were embedded in paraffin and sections 20 μ thick were cut. Newton's iodine-gentian-violet staining method (Huskins, C. L., *Jour. Gen.*, **18**, 315-364; 1927) was used with the above fixing agent. This gave a very brilliant stain, which seemed especially suited to differentiating overlapping chromosomes. In this respect it was preferred to Heidenhain's iron-alum hæmatoxylin, and it has also the advantage of being much quicker than Heidenhain's method. The foregoing method was used for the preparations shown in

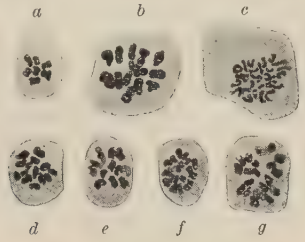

FIG. 1.

a, *A. Griffithsii*, 7 chromosomes; *b*, *A. Richardsonii*, 14 chromosomes; *c*, *A. Richardsonii*, root-tip, 28 chromosomes in the metaphase; *d*, *A. tenerum*, 14 chromosomes; *e*, *A. cristatum*, 14 chromosomes; *f*, *A. repens*, 21 chromosomes; *g*, *A. pungens*, 21 chromosomes. All but *c* show bivalent chromosomes in the metaphase of the heterotype.

Fig. 1, *a*, *d*, *e*, *f*, and *g*. The preparation shown in Fig. 1 *b* was made from a temporary mount prepared by Belling's aceto-carmine method, and this accounts for the swollen condition of the chromosomes. The root-tip preparation shown in Fig. 1 *c* was made from a slide prepared by using Bouin's fixing agent and Heidenhain's iron-alum hæmatoxylin stain.

On counting the chromosomes of the various species studied, they were found to fall into three groups with haploid numbers of 7, 14, and 21.

The groups are as follows:

A. Griffithsii	7	chromosomes.
A. Richardsonii	14	,,
A. tenerum	14	,,
A. cristatum	14	,,
A. repens	21	,,
A. pungens	21	,,

The accompanying illustrations are camera lucida drawings from slides showing clear counts. A Zeiss 1·3 mm. apochromatic objective and × 20 ocular were used in all cases. This gave a magnification of 3200 on the original drawings.

Only typical members of the species were used in determining these counts, and their chromosome behaviour was fairly normal in all cases. Lagging of one or two chromosome pairs was frequently observed in the anaphase of the heterotype in the species *A. pungens* and *A. repens*, and to a less extent in *A. tenerum*. However, the chromosomes did not seem to lag sufficiently to allow any possibility of their being excluded from the daughter nuclei.

Some of the wild plants examined did not exhibit normal chromosome behaviour. A plant which appeared to be *A. tenerum*, with the exception of short awns, was found to be peculiar in this regard. In the anaphase of the heterotype, three and four pairs of chromosomes were found at the equatorial plate just beginning to separate. This resulted in the daughter cells being multinucleate and containing varying numbers of chromosomes. There appeared to be eighteen univalent chromosomes at this stage, and the resulting daughter cells contained from five to thirteen. The plant of course was sterile. This may indicate hybrid origin, and the possibility of natural hybridisation occurring in the field. This phase of the subject, however, will be dealt with more fully in a later paper.

The discovery of a chromosome series in the Agropyrons is of considerable scientific interest as well as of practical value. This is particularly true, since like series have been reported in wheat, oats, and barley, all having a basic chromosome number of 7, and forming groups with 7, 14, and 21 as the haploid numbers. In wheat and oats the varieties of greatest commercial value belong to the 21-chromosome group, while in barley the 7-chromosome group contains all of our commercial varieties. The Agropyrons are intermediate in this respect. *A. tenerum* and *A. cristatum*, our two most promising economic species in western Canada, fall in the 14-chromosome group.

Further Evidence of the Carbon Isotope, Mass 13.

A FEW days ago Dr. King and I announced the discovery of an isotope of carbon, mass 13, appearing in the λ4737 Swan band of neutral C_2. Since then, I have found this isotope in two additional sources, namely, in Hopfield's absorption spectrograms of carbon monoxide, and in King's furnace (emission) spectrogram of the λ3883 CN band.

Two years ago J. J. Hopfield and I presented to the American Physical Society (*Phys. Rev.*, **29**, 922; 1927) an analysis of the emission and absorption spectra of carbon monoxide, based on extensive experimental material obtained by Prof. Hopfield with his vacuum spectrograph. The most complete absorption system is the fourth positive group, in which we were able to measure the bands from 0-0 to 15-0 (λλ1544-1199). These bands degrade to the red, and it was noted at the time that a faint second head appeared to the red of each main head, at a systematically increasing distance. We were not able, however, to fit these heads into the band system. I have now carefully measured these second heads and find that they agree quantitatively with $C^{13} - O^{16}$ as an assumed source. The heads can be measured with reasonable certainty in all the bands from 2-0 to 15-0, with the exception of two for which emission lines interfere. The calculated isotope shift, using reliable vibrational constants obtained by Prof. Hopfield and myself, varies from 0·072 mm. to 0·273 mm. (55 cm.$^{-1}$ to 316 cm.$^{-1}$). The arithmetical average *obs.-calc.* value is 0·0035 mm., and the algebraic average 0·0017 mm., in the sense that the observed shift is very slightly less than the calculated.

If the $C^{12} - O^{18}$ molecule is also present, its absorption bands should lie to the *red* of the $C^{13} - O^{16}$ band heads, by amounts varying from 0·006 mm. to 0·024 mm. It is thus impossible, with the present spectrograms, to separate the two isotopes. In all cases the observed $C^{13} - O^{16}$ head is wide enough to include a possible $C^{12} - O^{18}$ head. Thus the evidence is conclusive that $C^{13} - O^{16}$ is present, but is strictly neutral as to $C^{12} - O^{18}$.

The second source of information is King's furnace spectrogram of CN λ3883 (*Astrophys. Jour.*, **53**, 161; 1921). Dr. King kindly loaned me all his CN furnace spectrograms for my work on temperature and band spectra (*Astrophys. Jour.*, **55**, 273; 1922), and I still have this material. He directed attention (p. 162, loc. cit.) to a very faint series of doublets lying between λ3872 and λ3876. I measured these roughly, in connexion with my temperature work, but was unable to fit them into the band structure. I found, however, that two of the six doublets had been observed by Kayser and Runge in the arc spectrum. I now find

that these six doublets are the isotope lines P_{56} to P_{61}, due to $C^{13} - N^{14}$. They have the same doublet separation as the main doublets, and lie just to the red, in each case. In calculating the vibrational shift I have used the constants based on Heurlinger's original analysis, as calculated by Kratzer (*Ann. d. Phys.*, **71**, 72; 1923). For the rotational shift I have used new constants determined by R. T. Birge and W. O. Smith, in an unpublished quantum analysis of this band. The calculated shift varies from 0·228 mm. to 0·451 mm. (0·877 cm.$^{-1}$ to 1·739 cm.$^{-1}$).

Although the isotope lines are very faint, they can under favourable mechanical conditions be measured with reasonable accuracy. Excluding P_{56}, which lies too close to its parent line to measure properly, the observed isotope shift averages 0·014 mm. greater than the calculated, with an average deviation from the mean of only 0·0033 mm. This indicates a small error in the vibrational constants, or an electronic shift of this magnitude (0·05 cm.$^{-1}$). The latter explanation seems the more reasonable. The calculated isotope lines based on either $C^{12} - N^{15}$ or $C^{12} - N^{16}$ lie far outside the limits of error. There are definitely no other isotope lines observable in this region of the band, so that one may conclude that if isotopes of nitrogen exist, they are much less abundant, compared to N^{14}, than is C^{13} compared to C^{12}.

Fossil Records of Mendelian Mutants.

WITH the help of Prof. A. E. Boycott and others, I have been engaged for the past ten years in collecting data for the study of the distribution of variations in natural populations. The species selected for study were the two common and very variable British land-snails, *Helix* (*Cepœa*) *nemoralis* L. and *H.* (*Cepœa*) *hortensis*, Müll. These snails normally occur in populous and well-defined colonies. In habit they are sedentary and apparently seldom move far from their birth-place. Most of the variations taken into consideration are those that affect the colour and banding of the shell. The classical experiments of Lang, and the wider, but as yet mainly unpublished, work of Mr. A. W. Stelfox, have shown that several of the colour and band forms are inherited on simple Mendelian lines. Both species are recorded fossil from the Red Crag of Butley (Pliocene) and subsequent strata, and *C. nemoralis* from the Miocene of France (A. E. Ellis, "British Snails", 1926). Mr. J. W. Taylor in his monograph of the land and freshwater Mollusca of the British Isles gives numerous records of the geological distribution, and says of *C. hortensis* that in a pleistocene deposit (Ightham, Kent) the five-banded and unbanded forms were about equally numerous. To-day, bandedness is known to be a simple recessive to unbandedness in both species. Mr. W. J. Wintle (*Proc. Malac. Soc.*, **16**, 171-8; 1925) reports that on Caldey Island, *C. nemoralis* is very common as a living snail and as a pleistocene and holocene fossil. He states that among the living snails the unbanded form seems rather more common than the banded forms but that the reverse is true of the pleistocene shells. In neither of these cases, however, are any figures quoted.

In the living colonies studied by me the various phenotypes, as might be expected, occur with very different frequency; and the frequencies of any one phenotype may show a significant difference in samples separated by only a few yards. But on the whole series of colonies, banded types, taken together, are more prevalent than the unbanded form. Fortunately, the banding of the shell is easily seen in fossil material; detailed data, therefore, of the frequency of the different types in fossil samples could be obtained and would be of considerable interest from the point of view of genetics and natural selection theory. I am very grateful to Mr. A. S. Kennard, who has kindly supplied me with the figures for three fair-sized samples, each containing both species, from deposits near Goodwood. The samples are dated "Early Iron Age" and "Neolithic"; among the *C. nemoralis* there are four types, and among the *C. hortensis* two types, that are known to be inherited in a simple Mendelian manner. In all three samples the banded types taken together are numerically superior to the unbanded shells and the frequencies of the different types are just such as might be found to-day.

I need scarcely say that I should welcome any further data, references to already published data, or fossil material bearing on this point.

Mimicry.

PROF. MACBRIDE'S reply to my criticisms of his views on mimicry, which appeared in NATURE of May 11, has just reached me. Before this letter reaches England others may have dealt with this, but I would ask indulgence for a few remarks.

(1) It is to be regretted that opponents of the explanation of mimicry by natural selection so frequently rely upon arguments which overlook recorded facts. Such an argument was noted in section 9 of my article, and now Prof. MacBride quotes Bergh as evidence that butterflies are not eaten by birds. I would refer him to the discussion of this subject in Chapter x. of "A Naturalist on Lake Victoria", and to the following readily accessible publications: *Trans. Ent. Soc. London*, Part 3, pp. 353-71, 1902; *Proc. Ent. Soc., London*, pp. xxxii-xliii, 1915; *Jour. Linn. Soc.*, Zoology, vol. 33, 1919.

(2) Prof. MacBride states that the school to which I apparently belong gives no explanation as to how variations originate, and that "the real problem for science is how 'what is there' came into existence". That is one problem: another is why only a certain proportion of what came into existence survives to be included among 'what is there'. It appears to me that it is with the latter problem that mimetists are primarily concerned, as opposed to the former, which is one for geneticists.

(3) Regarding the influence of food, Prof. MacBride suggests that the study of such factors is the only means of solving the problems of animal coloration.

I would ask him to consider again the last paragraph of section 3 of my article, and whether he would attribute the wonderful similarity in appearance between *Planema* and *Pseudacrœa* to a similar effect of widely different food-plants upon larvæ not at all closely related to each other?

Statistics in Biological Research.

AWAY on holiday, I see in my copy of NATURE of July 20, p. 93, a letter on this subject from the distinguished statistician who uses the *nom de plume* of 'Student'. I regret that from some inadvertency he should have dated his letter from the Galton Laboratory, University College, London, an address to which, however much we may regret it, he has no claim. I feel sure that he will recognise, on fuller consideration, that the task of a director of a laboratory would become impossible if anyone could use its address without first obtaining the permission of the director.

KARL PEARSON.

The Bicentenary of Thomas Newcomen.

AMONG the vast number of ingenious inventors whose work is the heritage of to-day, a prominent place must be accorded to Thomas Newcomen, who invented the atmospheric steam engine. Newcomen died in London on Aug. 5, 1729, two hundred years ago. Steam power, which is now of universal application, drives our factories, propels our ships, transports our trains, and waters, drains and lights our cities, raises our minerals, ventilates our mines, irrigates our fields, and ministers to our needs in a thousand ways. If for certain purposes oil and gas have displaced steam, it should be remembered that the first airship, the first aeroplane, and the first self-propelled carriages were driven by steam, and the internal combustion engine itself owes much to the steam engine.

Newcomen's first engine, that near Dudley Castle, was erected in 1712. Fifty years later, similar engines were to be found all over Europe, and a hundred years after that the total horse-power of the steam engines of the world amounted to some twenty millions, while to-day this total runs into hundreds of millions. Whether we contemplate the crude constructions of Newcomen, the stately beam engines of a later day, the whirling high-speed engines which drove some of our first dynamos, or the magnificent machinery found in our ships and power houses to-day, we cannot but admire the skill, ingenuity, and resource which has given man so adaptable and so powerful a means of multiplying his efforts. The steam engine, indeed, has changed the character of our civilisation, and among all the hundreds of men who have applied their minds to the problem of steam power, none deserves recognition more than Thomas Newcomen.

"The engineer", it has been said, "pre-empts and conveys to society the benefits of the experiments and discoveries of the scientist. This contribution is vital; for he finds practical and economic obstacles that tax his ingenuity to the utmost; and the joy of solution, coupled with the satisfaction of achievement, is his reward. For success he needs all the knowledge the pure scientist has acquired and all the experience the man of practical arts has accumulated." This interdependence of abstract science and engineering progress is nowhere more clearly manifest than in the history of the steam engine. The engine of Newcomen was the outcome of the application of the physical discoveries of the seventeenth century; the greatest improvement in the engine during the eighteenth century was due to the discovery of the theory of latent heat by Black and Watt, while the appearance of Rankine's treatise on the steam engine in 1859, in which for the first time a sketch of the new science of thermodynamics was incorporated, marks another epoch in its progress.

The discussions of the present time on the properties of steam and the refined investigations on its pressure and temperature which are being made in a score of laboratories, have their seeds in the studies of the natural philosophers of Italy three hundred years ago, from which came the first thermometers and pressure gauges. Speaking of the applications of the forces of Nature to the promotion of human welfare, Simon Newcomb wrote: "The superficial observer who sees the oak but forgets the acorn, may tell us that the special qualities which have brought out such great results are expert scientific knowledge and rare ingenuity, directed to the application of the powers of steam and electricity. From this point of view the great inventors and the great captains of industry were the first agents in bringing about the modern era. But the more careful inquirer will see that the work of these men was possible only through a knowledge of the laws of Nature which had been gained by men whose work took precedence of theirs in logical order, and that success in invention has been measured by the completeness of such knowledge. While giving all due honour to the great inventors, let us remember that the first place is that of the great investigators, whose forceful intellects opened the way to secrets previously hidden from men." In doing honour to Newcomen, we therefore pay homage not only to a great inventor, but also to those students of science through whose work the steam engine became possible.

Of the Newcomen steam engine we know a great deal; of Newcomen's life very little. Born at Dartmouth and baptized in St. Saviour's Church on Feb. 28, 1663, he was the son of an Elias Newcomen and great-grandson of another Elias, who graduated at Cambridge in 1568–69, and for many years was rector of the pleasant parish of Stoke Fleming, near Dartmouth. Newcomen himself learned the trade of an ironmonger at Exeter, and afterwards had a business of his own in his native town. But no particulars from which we can form an estimate of his character have come down to us. His fellow-countryman, Thomas Savery, was his senior by about ten or a dozen years, and it was these two Devonshire worthies who first attempted to use fire and steam for pumping water for mines.

Savery's patent was obtained in 1698, and this included the plan of obtaining a vacuum by the condensation of steam. But prior to Savery's patent had come the invention of the barometer, the measurement of the pressure of the air, the invention of the air-pump, and the work of Torricelli, Pascal, and von Guericke had been succeeded by that of Boyle, Mariotte, and Hooke. Then, too, Huygens had made a piston descend by the weight of the atmosphere after he had obtained a vacuum beneath it by the explosion of gunpowder, and Denis Papin had afterwards suggested the use of steam instead of gunpowder.

This was the pregnant suggestion which was employed in very different ways by Savery and Newcomen—by the former unsuccessfully; by Newcomen with far-reaching effects. Newcomen's engine was like a gigantic balance. At one end

of a great beam hung the pump rods ; at the other hung a piston working in a cylinder, the cylinder being closed at the bottom and open at the top. The action of the engine was simple in the extreme. The cylinder having been filled with steam from a boiler beneath it, a spray of water was admitted to condense the steam and to form a partial vacuum. When this had been accomplished, the atmospheric pressure caused the piston to descend, thus raising the pump rods.

After the erection of the Dudley Castle engine in 1712, others were set up in Cornwall, Flintshire, the Newcastle-upon-Tyne area, London, Königsberg, Cassel, Paris, and in Sweden. No patent was ever taken out by Newcomen, but Savery's patent was considered to cover Newcomen's plan. The method of working naturally resulted in a great expenditure of fuel—about 25 lb. per horse-power per hour—but engines of the type were made until the beginning of the nineteenth century, and one or two were at work within the last twenty years.

The first great improvement in the engine came with Watt's experiment with the Newcomen engine model, still preserved at the University of Glasgow, which led to the invention of the separate condenser in conjunction with an air pump, a system which, as is well known, is still used in all condensing engines.

For a very long time Newcomen's merits were but little recognised. The Dartmouth antiquary, Thomas Lidstone, in 1857, and again in 1873, advocated the erection of a memorial to him at Dartmouth, and the project was at last carried out in 1921, the memorial consisting of a block of Dartmoor granite on which is a bronze plate with a line drawing of Newcomen's engine and an inscription.

Some Problems of Cosmical Physics, Solved and Unsolved.[1]

By Lord Rayleigh, F.R.S.

The Nebular and Auroral Spectra.

After the first period of success in identifying the origin of the spectral lines of the sun and stars with terrestrial materials, certain outstanding cases remained which were obviously important, but in which the identification could not readily be made. The first of these cases to yield was that of helium, which was unravelled while some of the pioneers in astronomical spectroscopy were still active.

Kindred to the hypothesis of helium, so triumphantly vindicated by terrestrial experience, were the hypotheses of nebulium, geocoronium and coronium. The problems epitomised by the two former words have now been solved, though the solution has taken quite a different turn from what was expected by the older generation of astrophysicists.

In the nebulæ are spectrum lines which have never been observed terrestrially. These are not faint members of otherwise complex spectra, such, for example, as we have in nearly all remaining unidentified lines of the solar spectrum, but they stand out, bold and challenging, on a dark background, presenting a puzzle that was the more intriguing from its apparent simplicity. According to spectroscopic experience, now made precise and rational, simple spectra are due to light elements. This, taken with the fact that lines known to be due to hydrogen and helium accompanied the nebular lines, strongly suggested that they too were due to light elements of the class which terrestrially are known as permanent gases. But the fact remained that no one had succeeded in observing them in the laboratory, and as time went on the originally convenient resource of relegating them to an unknown element had become less convenient. For the scheme of the elements became definite, and there was no room in it for new light elements.

More systematic knowledge of spectra in general, and of the spectra of the light elements in particular, was wanted before the question could be resolved. The clue was afforded by the circumstance that important nebular lines occur in pairs, obviously associated by their closeness and their constant relative intensity in different nebulæ and in different parts of the same nebula.

It is found, then, that the frequency difference of the green pair of lines originally discovered by Huggins, and known as N_1 and N_2, is 193 waves per centimetre. I. S. Bowen, to whom we owe the final elucidation of this enigma, sought for an equal interval in the spectrum of doubly ionised oxygen which he was analysing, and found it in the interval between the low-lying levels designated as P_2 and P_1. The lines were attributed to intercombination between one singlet upper level and two lower levels belonging to a triplet, the third being excluded by the rule of inner quantum numbers. To fix the differences of the terms concerned, it was necessary to connect the singlet and triplet levels by an intercombination line observed in the laboratory spectrum of doubly ionised oxygen. This was done by A. Fowler, who, combining Bowen's laboratory data with his own, was able to get a fairly satisfactory check on the observed position of the nebular pair. Practically no doubt remains, in view of the fact that other less well-known nebular lines can be similarly explained as due to singly ionised nitrogen and singly ionised oxygen.

The identification of these lines was made by ignoring so far as convenient the rules of the quantum theory. These rules forbid certain lines which might occur according to the combination principle. When a state of excitation of the atom is such that it cannot directly pass to a lower state without breaking one of these rules, that state is called metastable ; and this is the case which we have in the nebular lines.

The next cosmical problem I wish to refer to is the long outstanding one of the green line of the

[1] From the presidential address to Section A (Mathematical and Physical Sciences) of the British Association, delivered at Cape Town on July 24.

aurora, which was first seen by A. J. Ångström at Upsala in 1868. In this case the enigmatic line is even more isolated than in the case of the nebulæ, since, except in the case of unusually bright auroras, one can see nothing else in the spectrum at all. An apparently exhaustive study of the spectra to be obtained from terrestrial gases by the combined efforts of very many experimenters gave no clue to its origin.

The clue was eventually found by McLennan, who was able to produce the line by heavy electric discharges in a mixture of oxygen and helium, or, better, oxygen and argon. Oxygen is essential, and there is now no doubt that the aurora line is an oxygen line. There is, however, yet more to be done, for we do not know how to get the green line alone or with only the negative nitrogen bands as we see it in the sky. In the artificial spectrum the ordinary oxygen lines and the lines of the inert gas, helium or argon as the case may be, are conspicuous.

The wave-length of the auroral line could not be foreseen or calculated from our present knowledge of the arc spectrum of oxygen. In this case we have only a single line to deal with, and are thus without the invaluable clue afforded in the case of the nebulæ by the frequency separations of a doublet or triplet. There is, however, no difficulty in finding a conjectural place for it in the scheme of the oxygen arc spectrum as given by Hund's theory.

McLennan, arguing from the fact that nitrogen bands do not appear in the spectrum of the night sky, which, however, shows the green line, takes the excitation potential as less than 11·5 volts. This condition excludes very many possibilities. Indeed, if we are to be bound by the selection rules, it excludes *all* the possibilities. So with the example of the nebulæ before him, McLennan waives these rules, and assigns the green line to a transition from one or other of the low-lying metastable states which the theory indicates.

The lowest state of all should be a triplet, and owing to the absence of companions to the green line this may very probably be excluded. If so, only one alternative remains, and the successful determination of the Zeeman effect carried out in McLennan's laboratory is in harmony with the choice so arrived at. An independent investigation by L. H. Sommer, published immediately afterwards, covered exactly the same ground, and led him to the same choice. For the auroral line we have the experimental production from oxygen, but not the numerical spectroscopic relation. For the nebular lines our position is exactly the reverse.

There are other features of the auroral spectrum which are still obscure. I will limit myself to discussion of one of them—the red line of the aurora. Red auroræ are comparatively rare, and when they do occur the distribution of colour presents very curious features. In some cases the ends of the streamers are tipped with red, while the greater part of the length is green. The only reddish aurora which I have been privileged to observe at my home in the south of England (May 14, 1921) was of a different character, the colour ranging rapidly through various shades of purple. The light was distributed in irregular patches high up near the zenith, though predominantly in the north. At the same time its position was highly unstable, and the general impression produced was reminiscent of high potential discharges in highly exhausted vacuum tubes. Vegard has described cases where the whole sky suddenly turned crimson. He has obtained good small-scale spectrograms of the red line, which give the position as λ6322. A determination by V. M. Slipher of the Lowell Observatory gave λ6320.

So far as can be judged from the evidence available, no pair of the low-lying levels of the oxygen arc scheme which McLennan has discussed in connexion with the aurora are suitably placed to yield this red line by combination. We naturally turn to the consideration of nitrogen spectra, which, as is well known, are represented in the blue and violet regions of the auroral spectrum.

I described in 1922 a spectrum in which one of the first positive bands of nitrogen, λ6323, was very much intensified relative to the neighbouring red bands, which ordinarily are of comparable brightness. This spectrum was produced by adding a large excess of helium to the nitrogen afterglow, and the source had a visual red colour dominated by this band. In describing this work it was suggested as a possibility that this was the origin of the red auroral line, and somewhat similar ideas have been revived by McLennan in his recent Bakerian lecture. But there are difficulties to be met. One of the most urgent problems in auroral work is an adequate wave-length determination of this red line from a large-scale spectrogram.

Excitation of Spectra.

We have discussed cosmical spectra so far chiefly from the point of view of the spectroscopist. It will now be of interest to consider the probable mode of excitation of some of them.

Let us consider first the polar aurora; this, as is well known, is closely bound up with exceptional conditions of magnetic disturbance, and these in turn are conditioned by solar influence. As regards the nature of this influence, the theory of Birkeland, elaborated by Störmer, still holds the field. The sun is regarded by them as emitting localised streams of electrically charged particles from limited areas of its surface.

This theory in its original simplicity has required a good deal of patching, and it is difficult to feel much satisfaction with the special *ad hoc* hypotheses which have had to be introduced into it. A stream of particles with a charge of one sign only is open to the criticism that the stream will dissipate itself by electrostatic repulsion, and loses the hard outline which is one of the most essential features. Lindemann has proposed to get over the difficulty by making the stream neutral on the whole, still consisting, however, of charged particles of both signs. Here, however, we lose too much of the magnetic flexibility of the stream. Chapman proposes

(*Continued on p.* 199.)

Supplement to NATURE

No. 3118 AUGUST 3, 1929

The International Relationship of Minerals.

By Sir THOMAS HOLLAND, K.C.S.I., K.C.I.E., F.R.S.,
President of the British Association.

PRESIDENTIAL ADDRESS DELIVERED AT JOHANNESBURG ON JULY 31.

A FEW years ago, members of the British Association looked forward annually to a generalised statement of the results of their president's own research work in science. The rapid specialisation of science, with its consequent terminology, has, however, made it increasingly more difficult in recent years for any worker to express himself to his fellow-members.

Last year at Glasgow most of us expected that the hidden secrets of crystals would be revealed by one whose capacity for popular exposition accompanies a recognised power for extending the boundaries of science. Instead, Sir William Bragg released his store of accumulated thought on the relationship of science to craftsmanship in a way which gave each specialised worker an opportunity to adjust his sense of relativity and proportion.

If I attempted now to summarise my scattered ideas on the outstanding problems of micro-petrology, I might possibly find half-a-dozen members charitably disposed to listen, and of them perhaps one might partly agree with my theoretical speculations. We have indeed to admit that the science of petrology, which vitalised geological thought at the end of the last century, has since passed into the chrysalid stage, but, we hope, only to emerge as a more perfect imago in the near future.

Coincident with the excessive degree of specialisation which has developed with embarrassing rapidity within the present century, the problems of the Great War drew scientific workers from their laboratories and forced them to face problems of applied science of wider human interest; and the atmosphere of this great mining field—the Witwatersrand—stirs ideas of this wider sort—ideas concerning a field of human activity which, in recent years, has affected the course of civilised evolution more profoundly than seems to be recognised even by students of mineral economics. This must be my excuse for inviting you to consider the special ways in which the trend of mineral exploitation since the War has placed a new meaning on our international relationships.

With knowledge of the shortcomings which were felt during the War, in variety as well as quantity of metals, it was natural immediately after to review our resources, with the object in view of obtaining security for the future. But events have since developed rapidly, both in international relationships and in mineral technology. The evolution of metallurgy during the present century, and the developments in mining on which metallurgy depend, have placed new and rigid limitations on a nation's ability to undertake and maintain a war; consequently, the control of the mineral industries may be made an insurance for peace. Let us first consider briefly how these circumstances have arisen, how each country has passed from the stage of being self-contained in variety of essential products to the most recent of all developments, the change to large-scale production that has tended to the concentration of the mineral and metal industries in certain specially favoured regions which will hold the position of dominance for several generations to come.

BEGINNINGS OF CIVILISATION.

The names of Isis, Cybele, Demeter, and Ceres seem to suggest that the ancient theologians in different lands formed the same conception of those peculiar conditions in prehistoric times which made it likely that a woman—tied for long periods to the home-cave—rather than a man, was the one who first discovered the possibility of raising grain-crops by sowing seed. Whoever it was who first made this discovery was the one who diverted the evolution of man along an entirely new branch, and so laid the foundation on which our civilisation was afterwards built—the beginning of what Rousseau called "Le premier et plus respectable de tous les arts".

Compared with this economic application of observational science, the later inventions, which

seem so important to us—explosives, printing, the steam engine—were but minor incidents in the evolution of civilised activities. Previous uncertainty regarding the supply of the products of the chase, and the dangers which were necessarily attached to the collection of berries and edible roots in the jungle, became less important to the family-man when it was found possible to raise food-supplies nearer home. This discovery was thus not one of merely material advantage; for it necessarily led to the idea of storage, and so opened up a new mental outlook for primitive man.

Then this new possession of field-crops—the acquisition of cultivated real-estate—created fresh cares and new anxieties, which contained the germ of future political problems. In addition to the previous dangers from nomadic hunters and predatory carnivora, new troubles arose from other enemies — herbivorous animals, birds, insects, droughts and floods.

The formation of village-groups for protection, and the development later of tribal communities, resulted necessarily in the radial extension of field 'claims'—what our modern politicians, with careless disregard for geometrical terminology, now call 'spheres of influence'—always dominated by the extending necessities of agriculture, the growing of crops for food, and then, with the scarcity of skins, for textile materials.

The mineralogist and the metallurgist were perhaps before the farmer among those earliest research workers in applied science; but they were small folk, mere specialists in science. They have obtained a place of undue prominence in the minds of our modern students because of the adoption of their products for purposes of terminology in our conventional time-scale for those ages that preceded history. But this is due merely to the durability of implements as index 'fossils', and is in no sense a certain indication of their political and industrial importance.

Then afterwards, long afterwards—indeed, up to historically recent times—national boundaries became extended or were fought for, but still mainly because agricultural products in some form were a necessity for the maintenance of communal life. When British traders first went to India, for example, they extended their influence along the navigable rivers for the trade in vegetable products which were raised on the alluvial lands around; and so British India, as we call it to-day to distinguish the administered areas from the residual native States, is now mainly agricultural. Even when the permanent settlement of Bengal was made in 1793, no one thought of reserving for the State the underlying coal which has since become so surprisingly important. It was the field, and the field only, that was considered to be of commercial and political importance.

Agricultural products, therefore, until recently dominated the political ambitions of national units. Whether, and to what extent, the possession and use of mineral resources may now modify that dominant spirit is the principal question to which I wish to invite attention.

In the evolution of man, as in the evolution of the animals that occupied the world before him, there are no sharply defined, world-wide period limits: the pre-agricultural Bushman still survives and lives the life of pre-agricultural man in the Union of South Africa. The recognition of agriculture as a leading inspiration for acquiring and holding territory has been modified occasionally by 'gold rushes' into lands previously unoccupied, but they have generally had a temporary, often a relatively small, importance. The 'gold fever' may be what our lighter species of newspaper calls 'dramatic', but a fever is a short item in the life of a healthy man; heat-waves do not make climates. Possibly our school children are still told that Australia is noted for its goldfields, but the whole of the gold produced there since its discovery in 1851 is less in value than that of three years' output of Australian agriculture.

Even in South Africa, which produces half the world's supply of gold, the value of the metal is still less than that of the pastoral and agricultural products. It is true that gold and diamonds introduced temporary diversions in the political expansion of South Africa, but the dominant interests of the Union are still determined by the *boer-plaas* and the *weiveld*. The adventures of the Spanish *conquistadores* in the sixteenth century and of their enemies, the sea-roving Norse *buccaneers*, were inspired by stories of gold in El Dorado. Yet the whole of the South American output of gold, even under its modern development, is almost negligible beside the pastoral and agricultural products—wheat, maize, wool, tobacco, coffee, cocoa, sugar, meat, and hides. The total production of gold for the whole continent last year was worth no more than a hundredth part of the surplus of agricultural products which the Argentine alone could spare for export. Truly there is a substantial difference between the bait and the fish, between the sprat and the mackerel.

The discovery and colonisation of a continent are not the only ways in which the lure of gold has often brought results more valuable than the metal itself. The efforts of philosophers from the time

of the Alexandrian Greeks in trying to transmute the base metals into gold resulted in accumulating the raw materials with which Paracelsus laid the foundations of a new chemistry.

Mineral Resources and the Industrial Revolution.

Metals, we know, have been used since early times for simple implements and weapons, but it was not until the industrial revolution in Great Britain that the mechanisation of industries led to any considerable development of our mineral resources, first slowly and with a limited range of products, then on a large scale and with an extended variety.

However, to distinguish clearly cause from effect is not always simple. We were told at school of the remarkable series of inventors who laid the foundation of the textile industries in the north of England, and of the timely invention of the steam engine; its application to mine pumping; the successive construction of the steamer and the locomotive; the production of gas from coal. But the close association of ore, fuel, and flux made it possible not only to improve machinery, but also to increase facilities for the transport of raw materials and their products. When Josiah Wedgwood obtained his inspiration from the remains of Greek art, then being unearthed from the ancient graves of Campania, he first turned to account the raw materials of his native county of Staffordshire, and then promoted canal and road construction to introduce the china clay from Cornwall.

It is obvious that the growth, if not with equal certainty the origin, of the industrial revolution was due to the close association of suitable minerals in England. It was because non-phosphoric ores were still available that, at a later stage, Bessemer was able to give that new impetus which increased the lead of the English steel-maker; and so, when Thomas and Gilchrist came still later, with their invention of a basic process applicable to pig-iron made from phosphoric ores, their invention fell on barren soil in Britain. The new process, however, found applications elsewhere, and, instead of adding to the stability of the English steel industry, it gave the United States the very tonic they required, whilst the industrialists of Germany—where political stability had by then been established—found the opportunity of developing the enormous phosphoric ore deposits of Alsace-Lorraine, which had been borrowed from France eight years before. So it was through the genius of Sidney Gilchrist Thomas and his cousin Percy Carlyle Gilchrist that Germany was enabled in 1914 to try the fortune of war.

For the first half-century after the industrial revolution, Great Britain was able to raise its own relatively small requirements of iron as well as of the other metals that consequently came into wider use—copper, zinc, lead, and tin. The rapid expansion in steel production which followed Bessemer's announcement of his invention at the Cheltenham meeting of the British Association in 1856 brought with it the necessity of going farther afield for the accessory ores and for further supplies of non-phosphoric iron ores.

The next important step in metallurgical advance came in 1888, when Sir Robert Hadfield produced his special manganese-steel; for this led to the production of other ferro-alloys, and so extended our requirements, in commercial quantities, of metals which were previously of interest mainly in the laboratory—vanadium, tungsten, molybdenum, aluminium, chromium, cobalt, and nickel. The adoption of alloys, especially the ferro-alloys, at the end of the last century opened up a new period in the newly established mineral era of the world's history; for, beside the increase in the quantity of the commoner base metals which were wanted for the growing industries of Great Britain, it was necessary now to look farther afield for supplies of those metals that had hitherto been regarded as rare in quantity and nominal in value.

The country in which the industrial revolution originated and gathered momentum, because of the close association of a few base metals, could no longer live on its own raw materials, and never again will do so. Even in peace time Great Britain alone consumes twice as much copper and just as much lead as the whole Empire produces. Meanwhile, developments had occurred elsewhere, notably in Germany and in the United States, where the Thomas-Gilchrist process also had stimulated expansion. Thus, by the beginning of the twentieth century, the industrial activities of the world had entered a new phase, which was characterised, if not yet dominated, by the necessity for minerals to maintain the expanding arts of peace.

From this time on, no nation could be self-contained; a new era of international dependence was inaugurated, but the extent and the significance of the change were not consciously realised by our public leaders until 1914, when it was found that the developments of peace had fundamentally changed the requirements for war. Indeed, not even the German General Staff, with all its methodical thoroughness, had formed what the tacticians call a true "appreciation of the situation". Two illustrations of short-sightedness on both sides are sufficient for the present argument. Up to the

outbreak of war, although the wolfram deposits of South Burma were worked almost entirely by British companies, the whole of the mineral went to Germany for the manufacture of the metal, tungsten, which was an essential constituent of high-speed tool steel. Sheffield still occupied a leading place in the production of this variety of steel, but was dependent on Germany for the metal, which the Germans obtained mainly from British ore.

Under the compulsion of necessity, and without consideration of commercial cost, we succeeded before the middle of 1915 in making tungsten, whilst Germany, failing to obtain an early and favourable decision in war, used up her stocks of imported ore and turned to the Norwegian molybdenum for a substitute, until this move again was partly countered by our purchase of the Norwegian output. Germany then found that she wanted ten times more nickel than Central Europe could produce; so she imported her supplies from the Scandinavian countries, and they, being neutral, obtained nickel from another neutral country, where the Canadian ores—the world's main source—had hitherto chiefly been smelted and refined. We thus realised, not only our dependence on other lands for the essential raw minerals, but also we had the mortification of finding that, through our own previous shortcomings in the metallurgical industries, we were compelled to face lethal munitions made of metal obtained from our own ores.

The political boundaries of the nations, originally delimited on considerations dominantly agricultural in origin, have now no natural relation to the distribution of their minerals, which are nevertheless essential for the maintenance of industries in peace time as well as for the requirements of defence. This circumstance, as I hope to show in the sequel, gives a special meaning to measures recently designed on supplementary lines in Europe and America for the maintenance of international peace, measures which, as I also hope to show, can succeed only if the facts of mineral distribution become recognised as a controlling feature in future international dealings.

Localisation of Mineral Exploitation.

If minerals are essential for the maintenance of our new civilisation, they are, according to the testimony of archæology and history, worth fighting for; and if, according to the bad habits which we have inherited from our Tertiary ancestors, they are worth fighting for, their effective control under our reformed ideas of civilisation should be made an insurance for peace. In so attempting to correlate the facts of mineral distribution with questions of public policy, there is no danger of introducing matters controversial; everyone must agree on two things, namely, our desire and even hope for international peace, and consequently the necessity of surveying the mineral situation as developments in technological science change the configuration of the economic world.

Since the industrial revolution in Great Britain, the increase of mechanisation and consequent consumption of metals has been accelerated with each decade. It is not necessary to quote the statistical returns available for estimating the rate of this acceleration, for it can be expressed in a single sentence which justifies the serious consideration of every political economist: during the first quarter of this present century alone, the world has exploited and consumed more of its mineral resources than in all its previous history, back to the time when eolithic man first shaped a flint to increase his efficiency as a hunter.

To save you from the narcotic effect of statistical statements, I will limit myself to one illustration of this generalised statement; for this special example not only illustrates the rate of general acceleration in exploitation, but also introduces an important subsidiary question, namely, the way in which activity is becoming pronounced, if not substantially limited, to a group of special areas. In the year 1870 the United States produced 69,000 tons of steel; in 1880, $1\frac{1}{4}$ million tons; in 1890, $4\frac{1}{4}$ millions; in 1900, 10 millions; and in 1928, 45 millions.

Figures like these raise questions regarding the future which would take us beyond our present thesis. For the present we can assume with fair confidence that, taking the world as a whole, the depletion of natural stores is not yet alarming, although the rate of acceleration, by reason of its local variation, forces into prominence some international problems which will influence, and if effectively tackled will facilitate, the efforts to stabilise conditions of international relations.

I have elsewhere[1] made estimates of the quantities of metals stored in that part of the outer film of the earth's crust which may be regarded as reasonably accessible to the miner. The actual figures in billions of tons convey no precise mental impression to us, and need not be quoted here, but certain of the outstanding conclusions have a bearing on our present line of argument.

The first feature of surprising interest to the man

[1] Presidential address, Institution of Mining and Metallurgy, *Trans.*, vol. 34, p. lvii, 1925.

in the street is perhaps the relative abundance of those metals with which he is familiar in the arts—copper, lead, tin, zinc, and nickel. Nickel, in spite of its price and limited use, is twice as abundant as copper, five times as abundant as zinc, ten times as abundant as lead, and from fifty to one hundred times as abundant as tin. There are, indeed, among the so-called rare metals some which are distinctly more abundant than lead, although this is the cheapest of the lot in price, and is consumed at the rate of more than a million tons a year.

So one gets at once an indication of two important features. First, the miner works only those deposits in which the metal is concentrated sufficiently to make their exploitation a profitable business; and secondly, the metalliferous ores vary greatly in the completeness with which they have been concentrated in special places to form workable ore-deposits. Nickel-ore, for example, occurs under conditions which conspicuously hinder its freedom of local concentration; and consequently the wide distribution of the metal and its relative abundance bring little comfort to those who are anxious about their supplies of a metal which jumps suddenly into importance with every rumour of war. We are safe in predicting that we shall never recover for use in the arts any fraction of our total supplies of nickel as large as we shall of most of the others which have been mentioned. Indeed, nickel stands apart from the others; for, whilst it is important in peace time and is dangerously important during war, under the present state of mining and metallurgical practice the deposits in the world worth working for nickel can be numbered on the fingers of one hand, and nine-tenths of our supplies come from a single district in Canada.

Before discussing more precisely the significance of this and similar facts on the question of international relationships, let us consider for a moment the nature of our exploitation methods. Our reference to nickel shows that the metalliferous ores vary in their degrees of concentration, and, therefore, in their suitability for working; but, as the result of estimates made for a few common metals, we shall not be far from the average in assuming that we shall never recover more than about one-millionth of the total that lies within workable distance from the surface of our accessible dry land. Another conclusion, based on a similar group of calculations, shows that our greatest total tonnages are not contained in the rich deposits, but in those of low grade.

It follows, therefore, that every advance in metallurgical science and in mining technology that makes it possible to work our low-grade ores adds appreciably to the actuarial value of civilisation; for our mineral resources can be worked once, and once only, in the history of the world; and when our supplies of metalliferous ores approach exhaustion, civilisation such as we have now developed during the last century must come to an end. When a miner raises a supply of ore in concentrated form for the metallurgist, he damages, and so places beyond reach for ever, far larger quantities of residual ore than he makes available for use. When a metallurgist takes over the product of the miner and separates the refined metal for use in the arts, he also incurs serious losses, although not to the same extent. There are thus before both the miner and the metallurgist opportunities for extending the actuarial value of civilisation; and because the cost of labour is the principal constituent in the total bill, and has recently swamped contemporaneous advances in technology, the gradual elimination of manual labour by mechanisation is obviously the most profitable line of research.

Mechanisation carries with it in general a tendency to limit operations to the larger deposits, with the concurrent neglect of those propositions which are widely scattered over the earth, and, though individually small, represent in the aggregate a serious section of our limited resources. So our operations in mining, with the family of industries dependent on minerals, tend more and more to be restricted to a few special regions, where work can be done on a large scale.

The Mineral Age and International Relationships.

With this thumb-nail sketch of the way in which the new mineral era is developing, we are free to examine more closely the influence which this change in the configuration of the industrial world is likely to have on international relationships.

In the first place, it becomes obvious that no single country, not even the United States, is self-contained, whether for the requirements of peace or for the necessities of war. Not even the more scattered sections of the earth that are politically united to form the British Empire contain the full variety of those minerals that are the essential raw materials of our established activities.[2] Between

[2] For purposes of reference I give a list of minerals, showing how the resources of the British Empire, so far as our present information goes, can be relied on. This list has been kindly revised by Mr. T. Crook of the Imperial Institute.

1. *Those for which the world now depends mainly on the Empire*:—Asbestos, china clay, chromite, diamonds, gold, mica, monazite, nickel, and strontium.

2. *Those of which we have enough and to spare*:—Arsenic, cadmium, cobalt, coal, fluorspar, fuller's earth, graphite, gypsum, lead, manganese, salt, silver, tin, and zinc.

3. *Those in which we could be self-contained if necessary*:—Bauxite, barium minerals, felspar, iron ore, magnesite, molybdenum, platinum, talc, tungsten, and vanadium.

4. *Those for which we are now dependent on outside sources*:—Antimony,

them these two—the British Empire and the United States—produce more than two-thirds of the 2000 million tons of mineral that the world now consumes annually. Each of them has more than it wants of some minerals; but, in order to obtain its own requirements at economic rates, each finds it necessary to sell its surplus output to other nations. Each produces less than it wants of some minerals, and so must obtain supplies from other nations to keep its industries alive. Each of them is practically devoid of a few but not always the same minerals, which, though relatively small in quantity, are none the less essential links in the chain of industrial operations. Even if these two could 'pool' their resources, they would still be compelled to obtain from other nations the residual few. For it is important to remember that, unlike organic substance, it is not possible to make synthetic metals, and it never will be; it is not even possible to make artificial substitutes for many essential minerals that are used as such and not merely for their metallic constituents. There is no other mineral and no artificial substance, for example, that can combine the qualities which give to the mineral mica its position of importance in the arts—its fissility in thin sheets, its transparency to light and opacity to heat rays, its stability at high temperatures, its toughness and the degree of its insulating properties. There will never be a synthetic mica.

Thus the international exchange of minerals is an inevitable consequence of our new civilisation; and the cry for freedom of movement, for the 'open door' and for equal opportunity for development, comes into conflict with the unqualified formula of 'self-determination'. Whatever may have been possible before the industrial revolution, when the mineral industry merely contributed to the simple wants of agriculture, when most national units were self-contained, the formula of 'self-determination' has come too late in the world's history to do good without a more than consequent amount of harm. We cannot even live now without the free interchange of our minerals for those of other nations; in the name of civilisation we dare not go to war.

There is one more group of fundamental data to recall before we are in a position to point the practical lessons which follow from the newly established and prospective mineral situation. I have already referred to the way in which economic considerations tend, through large-scale production, to restrict operations to a limited number of specially favoured areas. There was a time within my memory when the primitive *lohar*, a survival of the aboriginal inhabitants of India, could be found in every province, nearly every district. He collected the granular mineral from the weathered outcrops of relatively lean iron-ore bodies, and, by using charcoal as a fuel, turned out blooms of malleable iron in a miniature clay furnace, using a pair of goat-skins to produce the necessary blast. These primitive workers also produced small ingots of steel by the carbonisation of wrought iron in clay crucibles many centuries before the same process made Sheffield famous.

With the large-scale production of steel in western countries, attended by the opening of the Suez Canal, cheaper transport by steamers and the spread of railways from the coast of India, the *lohar* has been exterminated from all but the most remote parts of the country. His history is similar to that of other workers; the small ore-bodies that he used are of no interest to the modern iron-master, and one result therefore of the modern movement is the neglect of a large fraction of our total resources. We are discussing, however, what is actually happening, not what we think should be a less wasteful course of evolution; natural evolution, like 'trial and error' methods, is always wasteful.

Primitive workers in various lands have opened up to relatively shallow depths but small deposits of other ores, and in eastern countries especially, where forms of civilisation extend far back into history, the numerous and widespread 'old workings' have given rise to travellers' impressions of great mineral wealth. But low-grade deposits that the ancient miner could not utilise are now opened up by mechanical methods on a large scale; and, on the other hand, what satisfied the primitive metallurgist in abundance would be of little use to the modern furnace.

We have now to re-value the tales of travellers, which have had a dangerous influence on those who have directed the course of international competition; we have to strike out of consideration the integers of the primitive worker to whom a great tonnage would form a mere decimal point in the modern unit; we have to realise that our mid-Victorian standards of metal production are gone for ever, and that the comforting after-War formula of 'back to normal' is merely a hypnotic drug to conceal the uncomfortable, one might say regrettable, dynamic conditions which have since developed at a speed that is not sufficiently recognised within our Empire.

It is now misleading to speak of the wide distribution of minerals within a country as we could

bismuth, borates, copper, petroleum, phosphates, potash, pyrites, quicksilver, sulphur, and radium.

A corresponding list for the United States was prepared in 1925 by a committee under the chairmanship of Prof. C. K. Leith, and published under the joint authority of the two Mining and Metallurgical Institutions in New York.

have done some fifteen years ago; we must now rule out the smaller deposits, and so form a new picture composed of those concentrations that are on a scale sufficient to support modern metallurgical units.

For this reason it is necessary to review afresh the resources of the undeveloped Far East, which has for many years been regarded as a menace to western industrial dominance. The vague general notion that mineral deposits are evenly distributed throughout the earth's crust has fed the impression that the development of China, which is much larger than the United States, may yet shift the centre of industrial gravity when her great population becomes awakened and organised by western technical science.

It is true that the people of the East are rapidly adopting the methods and using the mechanical facilities of western nations—railways, telegraphs, power factories, steel ships, and other metal-consuming devices; but the critical investigations made by mining geologists, especially since the War, tend, with a striking degree of unanimity, towards recognising the remarkable circumstance that China, as well as other countries of the Far East, is deficient in those essential deposits of minerals on which our mechanised form of civilisation is based.[3]

When China was still an unknown land, it was possible for after-dinner speakers to impress non-critical hearers by talk of the 'yellow peril' and the 'challenge of Asia'; but these expressions have been used without thought of the circumstance that natural resources in minerals now set a rigid limit to power, whether industrial or military. We have known for some time of the natural limitations of India, of Japan, and of smaller political units in the East; but until very recently we have had insufficiently precise data for estimating the quantitative value of the terms 'vast' and 'unlimited' which have been so often applied to China. Assuming that China may yet become a homogeneous national unit, or even assuming that her resources may become developed by Japanese energy, there is very little doubt now that, as an industrial area, the country is deficient in those minerals that form the essential basework of the modern form that civilisation has definitely taken.

The obvious limit in development, as defined by local natural resources, can be extended only to a limited degree by the importation of raw materials from other areas; for a country can buy metals only by the exchange of other products; its buying powers are limited by its selling powers. Abundant cheap labour, assisted by a semi-tropical climate, can produce an exportable surplus of foodstuffs only in limited parts of the Far East; even the so-called luxury products, which to our early navigators formed the inspiration of what we call geographical research, are now obtained elsewhere, and some are being replaced by artificial products evolved from the chemical laboratory.

Dominance of the Western World.

Exploratory work by mining geologists tends more and more to show that the essential mineral products are far from evenly distributed over the land areas of the world. Western Europe and North America have an undue share of those deposits that can be worked on a large scale, and it is the large-scale movement that marks the specialised character of the new industrialism. Anglo-Saxon character would have found limited scope for its energy but for the fact that nine-tenths of the coal, two-thirds of the copper, and as much as 98 per cent of the iron-ore consumed by the world come from the countries that border the North Atlantic. Dr. Wegener might like to add this fact to the data on which he has based his theory of drifting continental fragments.

The industrial revolution, which began in Great Britain, has always been recognised as a dominant phase in western civilisation, but it is now assuming a new character. It spread first to the western countries of Europe, and developed there because of the favourable conditions of mineral resources, but the force of the movement faded out towards the Slavic east and the Latin south; the mechanical industries of Italy are based on imported scrap. When the new industries became transplanted west of the Atlantic, the natural conditions which originally favoured Great Britain were found to be reproduced on a larger scale.

Thus in these two main areas, separated by the Atlantic Ocean, a family of industries based on mineral resources has arisen to dominate the world; for no similar area, so far as our geological information tends to show, seems to combine the essential features in any other part of the world. Other parts of the world will continue to supply minor accessories; and the isolated basic industries associated with coal and iron will supply local needs on a relatively small scale. But political control, which follows industrial dominance, must lie with the countries that border the North Atlantic.

It is only in this region that there is any approach to the state of being self-contained. Yet since the War there has arisen, first in Europe and then by

[3] A comprehensive study of this question, with bibliography, has recently been published by a competent and judicial authority, H. Foster Bain: "Ores and Industry in the Far East", 1927.

imitation in Asia, a degree of national exclusiveness more pronounced than any which marked international relations before 1914. Each small political unit has become vaguely conscious of the value of minerals, and has shown a tendency to conserve its resources for national exploitation on the assumption that they add appreciably to military security.

There is, however, no such thing now as equality of nations in mineral resources; 'self-determination' and the 'closed door' are misleading guides to the smaller nations. Political control may hamper, but cannot stem, the current of the new industrialisation; commercial and industrial integrations are stretching across political boundary-lines; and the demand for the interchange of mineral products will be satisfied in spite of fiscal barriers.

It would have been a shock to our members if, before the War, political problems were discussed from the presidential chair, and party politics may always be inconsistent with the mental products of culture. But the results of science and technology now limit the effects of national ambitions, and therefore dominate the international political atmosphere for good or evil. One is justified always in suggesting non-controversial measures that tend to good; and this it is proposed to do very briefly as the direct suggestion of the new configuration of the mining and metallurgical world.

The League of Nations has accomplished a large measure of international understanding in questions of social value; its influence in forestalling possible causes of war has raised new hopes; but fortunately, so far, it has not been compelled to use any such instrument of force as a blockade, and any such measure that clashed with the vital economic considerations of first-class powers would probably cause stresses well beyond its elastic limits. The more recent and simpler pact of Paris associated with the name of Mr. F. B. Kellogg wants equally an ultimate instrument for its practical enforcement.

It was with this ultimate object in mind that the outline of my argument was drafted after the Glasgow meeting last year; but I am glad to find that my views have since been expressed independently. Senator Capper, of Kansas, in February last submitted a resolution to the American legislature recognising this shortcoming of the simple treaty, and proposing to supplement its moral obligations by a corollary which, if passed, will empower the government on behalf of the United States to refuse munitions to any nation that breaks the multilateral treaty for the renunciation of war.

Senator Capper's resolution, however, still leaves unsolved a residual problem of practical importance. Those of us who had the painful duty of deciding between civil and military necessities in the Great War, know well that there is now but little real difference between the materials required to maintain an army on a war footing and those that are essential to the necessary activities of the civilian population; *materials* essential for one purpose can be converted to *articles* required for the other. Thus if Senator Capper's resolution be adopted by those who have signed the Kellogg Treaty, either sympathy for the civil population would be stirred, or the armies would be still supplied with many essential munitions: the definition of 'conditional contraband' would still remain as a cause for international friction.

A formula, still simpler but equally effective, is indicated by this review of the new situation arising from the essential use of minerals. It is suggested, therefore, as an amendment to Senator Capper's resolution, that the simple words "mineral products" be substituted for "arms, munitions, implements of war or other articles for use in war".

The only two nations that can fight for long on their own natural resources are the British Empire and the United States. If they agree in refusing to export mineral products to those countries that infringe the Kellogg pact, no war can last very long. As our friends across the Atlantic have recently learnt, it is easier to stop exports than to prevent imports: the Customs' officer is more effective, less expensive, and far less dangerous than a blockading fleet.

The confederation of American States has the advantage of forming a compact geographical unit, without inter-State fiscal barriers to hamper the interchange of mineral products. The British Empire, in the words of Principal Nicholas Murray Butler, "has passed by natural and splendid evolution into the British Commonwealth of Nations"; it is composed of geographically scattered and independent political units, among which freedom of interchange, with due regard to local interests, can be effected safely only by more complete knowledge of our resources. Next year the Empire Congress of Mining and Metallurgy will meet in this city to discuss the proposition which I submitted to it at Montreal in 1927; and this address must be regarded, therefore, as an introduction to a movement which one hopes will supply the necessary data, and so facilitate a working agreement between the two great mineral powers that alone have the avowed desire and the ability to ensure the peace of the world.

Summaries of Addresses of Presidents of Sections.[1]

Geology in Colonial Development.

Sir Albert Kitson, who is the Director of the Gold Coast Geological Survey, in his presidential address to Section C (Geology), discusses "The Utility of Geological Surveys to Colonies and Protectorates of the British Empire". Geological surveys are now in full operation and doing valuable work in Nigeria, the Gold Coast, and Sierra Leone in West Africa; in Uganda, Nyasaland, the Anglo-Egyptian Sudan, and the Mandated Territory of Tanganyika in Central and East Africa; and in the Federated Malay States. Many other colonies have had temporary surveys.

After discussing in detail the functions and methods of such surveys, Sir Albert shows that special assistance may be given to various other departments, such as those devoted to agriculture, forestry, water supply, and public works, the latter involving problems of hydro-electric power and sanitation as well as materials of construction and foundations. Some of the practical results achieved by existing surveys have been of great material value. The coal field of Southern Nigeria, discovered in 1909, has so far yielded two and a half million tons of coal, the total net profit to Government being £452,559 to Mar. 31, 1928. The total cost of the Nigerian surveys to the same date was £88,700, less than one-fifth of the profit from one single discovery. In the Gold Coast the specially important discoveries made by the Geological Survey are huge deposits of manganese ore (total production to Mar. 31, 1928, valued at £3,350,706); more than 250 million tons of high-grade bauxite, still undeveloped for lack of railway communication; and diamonds, those found since 1921 being valued at £1,758,348. The export duty received last year by Government from diamonds alone was nearly $2\frac{3}{4}$ times the cost of the Geological Survey for that one year.

The recently established Sierra Leone Geological Survey has already led to the development of large deposits of hæmatite and of alluvial gold and platinum. In Nyasaland, discoveries of deposits of various minerals have been so promising that a prospecting company has been formed with the view to their thorough examination. In Uganda, mining companies and prospectors are advised of areas likely to prove valuable, the normal operations of the Survey being so far mainly geological mapping. Here, moreover, a unique feature is the recent establishment of a seismological station.

Many important discoveries by the above and other geological surveys are also referred to, as well as the invaluable work carried out almost everywhere in connexion with water supplies, constructional materials, and engineering schemes. Sir Albert gives detailed evidence of the great value of geological surveys to young countries, through the application of scientific knowledge and methods, both theoretical and practical, to the discovery of the resources of Nature.

Adaptation.

The general thesis of Prof. D. M. S. Watson's presidential address to Section D (Zoology) is that since adaptation lies at the very foundation of the Darwinian or Lamarckian views of the method of evolution, the assumptions concerning adaptation ought to rest upon the clearest of evidence. A cursory examination shows, however, that this is not the case. Instead, the assumptions that every structure in an animal has a definite use in the animal's daily life or in its life-history, and that an adaptation, that is, a change in structure and by implication also in the habits of an animal, rendering it better fitted to its "organic or inorganic conditions of life", often rest upon no sort of observational basis. Amongst the examples of such fallacious argument cited is that of the enormous development of the depth and complexity of the teeth in the phylogenetic series leading to the modern horse. This alleged adaptation to a change in the food and feeding may be no more than a development associated with the greatly increased bulk of modern horses (fifty times that of their Eocene forerunners), the sustenance of which demanded more food and postulated greater wear in the teeth.

Not all cases of so-called adaptation are so uncertain, but it is vital that investigations should be carried out to decide whether there is any general occurrence of such special relationship between structure and habit, and whether, if it occurs, it is rightly to be regarded as of adaptive origin. In the solution of this pressing problem, physiology, and especially experimental physiology, is likely to play one of its most important rôles in zoological science.

The whole theory of natural selection is based upon the efficacy of specific differences, but the extraordinary lack of evidence to show that the incidence of death under natural conditions is controlled by such small differences, or by physiological differences correlated with such structural features, makes it difficult to appeal to natural selection as the main, or indeed an important, factor in bringing about the evolutionary changes which we know have occurred. At present, its real existence as a phenomenon rests on an extremely slender basis.

The occurrence of a direct environmental effect upon structures, strongly hinted at in some recent experiments, may do away with the need of postulating adaptive changes in, say, the pale coat-colours characteristic of arid regions. Further, the hypothesis that the variable characters separating one geographical race from another are due to a number of genes, all independent and all producing similar effects, may lead to an explanation of the divergence of local races of a species.

[1] The collected presidential addresses delivered at the meeting are published under the title "The Advancement of Science, 1929". The volume is obtainable at 6*s*. of all booksellers or from the British Association, Burlington House, London, W.1.

In short, the present position of zoology is unsatisfactory. We know as surely as we shall ever know that evolution has occurred, but we do not know how this evolution has been brought about. The data so far accumulated are inadequate in character to allow us to determine which, if any, of the proposed explanations is a *vera causa*. It appears, however, that the experimental method rightly used will in the end give us, if not the solution of our problem, at least the power of analysing it and isolating the various factors which enter into it.

Science and Engineering.

The address of Prof. F. C. Lea, president of Section G (Engineering), entitled "Science and Engineering", emphasises the importance of fundamental scientific discoveries and the scientific method in modern engineering developments, and suggests that the only hope of solving many of the problems which face the engineer to-day is by supplementary experience with organised experiments.

Engineering is much older than modern science. In the ancient civilisations great engineering works were carried out, but for two thousand or more years little or no progress in structural engineering took place and there was no development in prime movers. The revival of experimental work in pure science, after the fall of Constantinople, led to discoveries of great fundamental importance, and eventually to the development of the steam engine in the seventeenth and eighteenth centuries and to the discovery by Faraday of the fundamental principles of the modern dynamo and electric motor in the nineteenth century.

During the past century very remarkable developments have taken place in structural engineering, and in this development experiment combined with mathematical analysis has played an important part. Thus the important steps made in engineering in recent times, which distinguish the nineteenth and twentieth centuries from all preceding ones, were commenced and made possible by fundamental discoveries in science, and it can be safely anticipated that no new epoch-making developments in the future will be possible unless preceded by new fundamental scientific discoveries.

Having recognised the debt of engineering to pure science for the discovery of new principles and new facts, only part of the story has been told. In the workshop, in design, in choosing materials, very considerable difficulties had to be overcome by the engineer before success was possible. Inventive ability allied with experiments, research in the development of new materials for tools and machine elements, the perfection of machine shop methods, have all contributed, but wherever success has been sure the methods of science have been followed. To-day there is a serious demand being made upon the engineer to utilise the energy resources of the world more efficiently, but the only hope of real progress is in combined laboratory and workshop research and in the development of new technique. In a matter of such vital concern to industry and the community, much more rapid progress could be made if public organisations and the large power-distributing companies and authorities, as well as private firms, accepted the responsibility of the provision of funds for research. In the universities, fundamental work is being carried out, and much more can be done if funds are available; the National Physical Laboratory is doing work of the greatest value, but it is important, yea imperative, that the same scientific methods that guide fundamental work should be used in industry.

There are many problems of vital interest to modern civilisation in connexion not only with the production of power and the utilisation of sources of energy, but also related to structures and materials, upon which the safety and comfort of thousands of people may depend. These problems can only be solved by supplementing the accumulated experience of engineers by direct experiment and research.

The engineer is faced with many unsolved problems, to many of which he must find immediate, if only approximate and tentative, solutions. If experimental science and mathematics cannot yet give him an exact solution, he must still carry on, and in this way much has been achieved. Not infrequently engineers become impatient of science and lay too great emphasis upon experience; but as an effective guarantee of future progress and in the solution of many problems in design, in processes, in materials, as well as in the discovery of new methods, it is necessary, as Francis Bacon would to-day remind us, to apply "natural philosophy . . . to particular sciences, and particular sciences [must] be carried back to natural philosophy".

Archæology in South Africa.

Mr. Henry Balfour's presidential address to Section H (Anthropology), under the title "South Africa's Contribution to Prehistoric Archæology", reviews the conditions of archæological study in the Union. There are few regions which now remain unsearched for traces of early man. Interest in the problem becomes more intense as it is found that the scattered materials belong to one huge complex. Unfortunately, the opportunities for study offered by recent primitive peoples living in the stone age have been neglected. As in the case of the Tasmanians, so the Bushmen of South Africa are passing away and little light can be thrown by the straggling survivors on the true character of Bushman culture. Even the rock paintings and engravings must be studied archæologically. Yet we can note with satisfaction a steady growth in South Africa of a keen interest in archæological problems. There is abundant stimulus to field workers.

It is manifest that the vast African area south of the Zambezi holds an unparalleled wealth of archæological material due to the arrival of a succession of immigrant peoples from North Africa. South Africa is a *cul de sac*, and the less advanced in culture have been forced down to the *cul de sac*. During long ages this sequence of irruptions has resulted in a congestion of heterogeneous ethnic elements leading to an accumulation of culture

relics. The overlapping of cultures led to fusion and confusion, producing complex hybrid industries the elements of which it is the aim of local archæologists to unravel. This is now proceeding apace, thanks to many keen researchers.

The great scientific interest of this material imposes certain responsibilities on the administration. Organisation of research to avoid unprofitable work is desirable, and a carefully selected advisory committee should be appointed. At the present time it is not so much abstract theories as concrete facts that are wanted to establish the relative antiquity, sequence-position, and characteristics of the early industries, their geographical dispersal, routes of migration, and their inter-relationship. One problem requiring careful scrutiny is the evidence of man's antiquity in the Zambezi gravels, where implementiferous gravel drifts lie 400 ft.-600 ft. above the present level of the river in the gorge. One of the most interesting questions for local archæologists is the true culture horizon of the Still Bay industry, of which the finely chipped leaf-blades have by some been taken to be Solutrean, though the technique appears to differ from that of the Solutrean blades of north-west Europe.

Another interesting problem is the 'Kwè, a digging-stick weight of the Bushmen which, on the analogy of other areas, seems out of place in a people whose culture suggests palæolithic affinities. The art of perforating hard stone is in Europe a late development. Did the Bushmen in their southward drift come into contact with some such people as the Gallas, in whose comparatively advanced culture the perforated stone would not be remarkable ?

In South Africa characteristic neolithic types are absent. The transition from stone to iron is abrupt, and there is an absence of linking cultures —a wide unbridged culture hiatus. Although the industries successively introduced offer analogies to the early stone age industries of Europe, and they may be regarded as offshoots from them, it is highly improbable that they synchronise. A migrating culture cannot long continue unchanged. It reacts to new environmental conditions. Certain elements in the complex persist and offer affinities with distant cultures. South African archæology intriguingly suggests culture affinities far ranging in time and space, and also illustrates how they have become attenuated and obscured in the course of long migration.

Problems of Palæobotany.

Prof. A. C. Seward's presidential address to Section K (Botany) is entitled "Botanical Records of the Rocks, with special reference to the Early *Glossopteris* Flora". After dealing very briefly with the earlier chapters of the history of the plant world, with special emphasis on the relatively enormous lapse of time represented by the rocks of the earth's crust older than those which have afforded the records of the oldest known terrestrial plants, a general description is given of the early Carboniferous vegetation and of the richer and more varied vegetation of the latter part of the Carboniferous period. Special attention is directed to the vegetation of the great southern continent of Gondwanaland, which included India, Australia, South Africa, South America, and Antarctica.

The geological age of this southern vegetation—the *Glossopteris* flora—has long been under dispute : it is generally agreed that there was a glacial period of long duration in Gondwanaland when the *Glossopteris* flora was being evolved. Some geologists, notably Prof. Schuchert of Yale University, refer the Palæozoic Ice Age and the early stages of the *Glossopteris* flora to a Permian age ; others believe that glacial conditions prevailed and that the *Glossopteris* flora had already established itself over an enormous area in Gondwanaland before the end of the Carboniferous period.

In other words, the question is : Was there an Ice Age in the region which is now India and in the southern hemisphere at a time when the later Carboniferous vegetation flourished in the northern hemisphere ; or were the Ice Age and the *Glossopteris* flora subsequent to the luxuriant forests of the Coal Age, which covered a considerable part of the world north of the equator ? Evidence recently brought forward by Prof. Schuchert in favour of a Permian Ice Age and *Glossopteris* flora are critically considered. The conclusion reached is that if we could transport ourselves back through the ages into a forest of the northern hemisphere in the latter part of the Upper Carboniferous period, and thence travel by aeroplane to the land that is now South Africa, we should find retreating glaciers and a vegetation in which *Glossopteris* and *Gangamopteris* were prominent plants.

The differences between the Palæozoic and the Early Mesozoic floras is mentioned, and the hope is expressed that a more thorough investigation of South African fossil plants may supply valuable information on the evolution of floras at the critical stage in the history of the plant-world, which occurred at the close of the Palæozoic era. A brief reference is made to the value of fossil plants as tests of climate. The geographical distribution of plants of former ages indicates that climatic conditions in Arctic and Antarctic regions at several geological periods were much more genial than those at the present day. It is pointed out that while there is a tendency to rate too highly the value of extinct plants as guides to climatic conditions, the occurrence of rich Palæozoic, Mesozoic, and Tertiary floras well within the Arctic Circle presents a problem which has not yet been satisfactorily solved. Methods of dealing with this problem are suggested. Finally, reference is made to the importance of studying the geographical distribution of fossil plants with a view to a better understanding of the present distribution of floras over the earth's surface.

Throughout the address allusions are made to lines of inquiry which might profitably be followed in South Africa by students interested in problems connected with the development of the world's vegetation. Prof. Seward pleads for a wider recognition on the part of geologists and botanists, whether professionals or amateurs, of the value of palæobotanical studies in relation to problems of general interest.

Agriculture and the Empire.

Sir Robert Greig, president of Section M (Agriculture), deals in his address with the development of the agricultural resources of the Empire as an obvious means of adding to the wealth of the world. He points out that as trustees for the native populations in the tropical and semi-tropical possessions, development of its natural resources is forced upon the Empire. Administration alone, however good, is not enough; only by increasing the wealth-producing power of these populations can their well-being be secured through better education, sanitation, and freedom from malnutrition and preventable diseases.

The resources of the Empire are mainly agricultural and largely undeveloped. Even in India, the most intensively cultivated part of the Empire, the cultivable waste land is equal to half the present cultivated area, and in Canada, Australia, and South Africa only two or three acres in every hundred are cultivated.

The application of science to the problems of agriculture has already great achievements to its credit. The organisation of research for the development of the Empire offers almost incredible possibilities. But to obtain the best results it is necessary to regard the Empire as a single organism. From this point of view the problems can be outlined, information collected, a campaign planned, and money and men found to undertake research. Conditions are more favourable now for co-operation in research than ever before.

The Committee for Civil Research is in a position to inquire into any non-military problem. The Empire Marketing Board is able to provide funds, and the newly constituted Imperial Bureaux of Agricultural Research can collect and make available the literature on whatever may be the subject of inquiry. These Bureaux, it is hoped, will form a gathering ground for theories and theorists, will act as illuminants and expositors, and eventually as finger-posts to new and profitable roads and by-paths of research.

Thus machinery exists whereby a problem in nutrition, genetics, pathology, economics, or any other science may be attacked simultaneously in different parts of the Empire by many workers acting together. Success has already followed such team work when applied to the investigation of the mineral content of pastures in such widely separated areas as Scotland, Kenya, Australia, and the Falkland Islands.

The problem may arise in several ways: As the idea of some research worker who finds himself unable alone and unaided to deal with it; as the conception of a department of agriculture faced with losses due to animal diseases or crop pests; as the desire of a community to grow and market a new product; or as a clue which emerges from the collection of information by the Imperial Bureaux of Agricultural Research.

The main thing is that the opportunity exists. The Empire presents the largest and finest outdoor laboratory in the world. It provides the greatest extent and variety of facilities for research. The systems of government make it possible, through the Imperial connexion, to co-operate without difficulty or embarrassment. The machinery for co-operation is in being. Funds are available.

By taking thought, and by regarding the agriculture of the Empire as one field for general and comprehensive development, the well-being and prosperity of the nations of the Empire can be increased, and ultimately the wealth of the world as a whole.

Printed in Great Britain by R. & R. Clark, Limited, *Edinburgh.*

to retain a slight excess of charge of one sign, and in this way is able to arrive at a tolerable compromise.

The search for direct evidence might not seem at first sight very hopeful, but not long ago a sensational suggestion was made by Störmer. His attention was directed by Hals to echoes heard after short-wave (131 metres) wireless signals sent out from Eindhoven in Holland. These echoes have been found by Störmer and Hals at long intervals up to as much as fifteen seconds after the original reception. Now, if we bear in mind that with the velocity of light the longest terrestrial distances only give intervals about $\frac{1}{7}$ sec., it seems inevitable that some extra-terrestrial reflector should be looked for. Störmer finds this in the corpuscular stream as bent round by the earth's magnetic force. Though the boldness of the idea is staggering, it is difficult to suggest any alternative view.

T. L. Eckersley has made an observation on electrical disturbances of natural origin which he interprets as analogous to Störmer's. A click is heard in a telephone attached to a large aerial, which is followed at an interval of about three seconds by a 'whistler' or musical note of short duration. Further whistles follow at intervals of 3·8 sec., each more drawn out than the previous one. The musical notes are regarded as due to the spreading action of a dispersive medium on an electrical impulse. It is only at times of magnetic storm that these phenomena are frequent. Further development of observations of this kind will be awaited with keen interest.

To return to the nebular spectrum: although the main problem has been cleared up in the way described, it would still be an important step to imitate the spectrum in the laboratory, not so much to confirm the origin of the lines as to get direct information about the conditions under which they may be excited. A large volume and high rarefaction (rarity of collisions) is suggested by the nebular conditions, and was plausibly held by Bowen to be an essential. It must be allowed, however, that such experimental evidence as we have at present on passage downwards from metastable states does not definitely point in this direction.

Metastable States.

In discussing the nebular and auroral spectra, we encountered the idea of 'metastable states'. At present this conception is not in a very satisfactory condition. The original idea was of a state which did not allow of direct transition by emission of radiation to the stable ordinary state. Let us compare the levels of the atom to the stories of a building and the optical electron to a man inside the building. The ordinary state of the atom is represented by the man being on the ground floor, and the metastable state by placing him on the first floor. But the internal architecture of our building must be pictured as peculiar. A staircase connects the first floor with the second floor, and another staircase connects the second floor with the ground floor: but there is no connexion between the first floor and the ground floor except by going up higher and coming down again.

Facts which have since come to light require some revision of this. In the nebulæ the electron manages somehow to escape from its prison-house and descend to the level below, not by the legitimate route of going upstairs and down again, but by illicitly breaking through the floor. Abandoning the metaphor, the selection rule which forbids transitions not involving a change in the azimuthal quantum number is violated in all such cases. The inner quantum number rule, which requires that the inner quantum number should not change from 2 to 0 or from 0 to 0 is also violated in one class of cases, and rather meticulously observed in another. This rule permits only the pair of green nebular lines in doubly ionised oxygen which we have discussed; and in deference to it only two are observed, instead of the three which apart from this might have been expected from the triplet ground state. Yet we find the blue singlet line λ4363 of this ion violating the same rule, and the same applies to the analogous case of the aurora line.

In the case of the mercury spectrum, which lends itself well to experimental observation and of which much detail is known, we have laboratory examples of the violation of this rule, as originally shown by experiments of Takamine, Fukuda, and other Japanese physicists. The lines were originally obtained under conditions where a strong electric field was acting, and this was sometimes urged in mitigation for breaking the rule. Again, the lines were of low intensity, and this too was thought to be a partial excuse.

Whatever might have been thought of these apologies originally, their irrelevance was, I think, clearly shown in some experiments of my own, in which one of the 'forbidden' mercury lines was obtained as the second strongest line in the entire mercury emission spectrum, in the vapour passing through a discharge, but altogether away from the region in which the discharge itself was taking place, and consequently in the absence of an extraneous electric field.

In another experiment I was able to obtain the other forbidden line as an absorption line in unexcited mercury vapour, and thus apparently in the absence of any disturbing conditions. In this experiment the quantity of vapour used was very large, about ten million times the amount required to bring out the resonance line of mercury in absorption. The probability of the transition thus indicated is very low, and for the other forbidden line it is apparently still lower. But for all that, as we have seen, this forbidden line can be got in considerable intensity in emission.

The necessary condition in the mercury experiments appears to be a large accumulation of mercury atoms in the relevant metastable state, so that, even with a low probability of transition for the individual excited atom, a considerable number of transitions occur. It has even been proposed to define a metastable state as one with a low probability of transition. This takes us far from the

original conception, and makes 'metastability' merely a question of degree. If this conclusion is accepted, a far-reaching revision of our present notions may become necessary. The general softening of outline on our picture of atomic events resulting from the substitution of wave groups for particles seems likely to afford what is required, and allow the occasional transition downwards from a metastable state.

Unknown Elements of High Atomic Weight.

Although we are no longer at liberty to postulate unknown light elements, we are free up to the present to postulate heavier ones than any known terrestrially. Jeans, as is well known, has made use of this hypothesis to explain the origin of stellar energy. In common with other authorities, he provides it by the destruction of matter, with radiation of the equivalent quantity of energy (mc^2) demanded by the theory of relativity. So far there seems to be fairly general agreement. The difficulties arise when we come to the question of stability, and here agreement is not general. Jeans considers that the source must liberate energy at a rate independent of the temperature. I am not qualified, and shall not attempt, to discuss this point. The object of postulating unknown heavy elements is to endow them with the property of going out of existence spontaneously at a rate which is independent of external conditions, except in so far as ionisation, which involves the removal of some of the electrons from the neighbourhood of protons, tends to hinder the process.

In the known radioactive elements we have, of course, instances of unstable forms of matter, and Jeans regards these as transitional; but it must be admitted that substances which undergo spontaneous disintegration do not at first sight form an altogether satisfactory half-way house between those which are quite stable on one side and those which spontaneously go out of existence on the other. Then we have to explain why these heavy atoms are not found on the earth, which, it is generally agreed, originally formed part of the same mass as the sun. Jeans mentions this difficulty, and gives reasons for thinking that the heavy elements would sink to the interior of the mass, so that the earth, formed from the exterior part of it, would not contain them. That a *vera causa* is here appealed to cannot be doubted; but there seem to be some difficulties in assuming that it operates with enough precision to secure the desired result.

The list of known elements ends with uranium, and we must notice that of the occupants of the 92 places in the list up to and including uranium, nearly all answer to their proper numbers when the roll is called. The only exceptions are 85 and 87; and he would be a rash philosopher who attached much importance to these vacant places, which may be filled up any day. Roughly speaking, we may say that the elements up to uranium are all present, and the higher members assumed to exist in the stars are all absent. It is putting a heavy burden on the mechanism of gravitational separation to expect it to achieve this result. The inventors of ore-dressing machinery would, I should imagine, despair of accomplishing anything like it.

Nature works on a vast scale and with plenty of time at her disposal, and it may well be urged that we must be careful of measuring her possible achievements by our own. We may ask, however, whether the more direct indications available suggest that she has in fact made this separation. If there is this cut between the atomic numbers 92 and 93, we should expect most of 92 to have gone into limbo in order to ensure the *whole* of 93 having done so. Yet 92 (uranium) is a relatively abundant element compared with most, being in fact No. 25 on the list of abundance in igneous rocks. Again, we happen to be in a position to say that, on the earth at least, uranium, so far from having sunk to the centre, is concentrated near the surface.

Assuming that uranium exists on the sun as on the earth, then, as first pointed out by Lindemann, there are strong grounds for thinking that it must be in course of formation there, for the life of uranium is too short in comparison with the probable age of the sun to allow us to suppose otherwise. Those who remember the early development of radioactivity will recall that a parallel argument was successfully used by Rutherford to prove that radium must have originated on the earth before the fact was directly proved that it is being generated here. Radium (it was later shown) is generated from a parent body of higher atomic weight, namely, uranium. Jeans would regard the origin of uranium itself as analogous, and if this analogy is accepted it would require the presence of an element of still higher atomic weight, capable of undergoing radioactive disintegration, but, it is to be observed, incapable, *ex hypothesi*, of dissolving entirely into radiation.

No doubt these are very deep waters, and we can scarcely expect at present to fathom them. What would really be most helpful would be a theory of atomic structure in sufficiently definite agreement with experiment as regards known elements to enable us to proceed to investigate the properties of elements of higher number than 92 with confidence.

On the general question of whether the evolution of elements has proceeded from the simple to the complex, or from the complex to the simple, it does not seem to me very much to the purpose to appeal to evolutionary doctrine and the analogy of organic evolution, in favour of the former alternative. Is it not more to the point that radioactive changes are of the latter class? At present this is a question of scientific taste. Perhaps it is not irrelevant to remark that even in organic evolution degeneration of organisms sometimes occurs, and I do not know whether our biological colleagues are in a position to assert that the whole course of organic evolution may not at some future time be reversed by a change of conditions. At all events, it is something to have formulated the more restricted question of whether uranium now comes into being on the sun by a synthetic or an analytic process. It would seem that this is a well-framed question, and that the answer can scarcely be either *both* or *neither*.

Physiology the Basis of Treatment.[1]

By Prof. W. E. DIXON, F.R.S.

THE ultimate aim of medicine is the prevention or cure of disease: this practical aspect so far dominates all others that it is often referred to as the healing art; indeed, it is difficult to think of medicine apart from treatment.

The term 'physiology' is usually used to designate the science of function, whether it is studied in broad outline and dealing with the mechanism of action or as the physico-chemical mechanisms leading up to this action. Disease means the unusual functioning of tissues which may be the result of accident, hereditary weakness, or parasitic organisms. Generally it is wrong to speak of this as malfunctioning: the unusual functioning is physiological and perhaps the best for the organism under the unusual conditions. The science of medicine, then, is nothing more than trained and organised common sense based on physiology. It is still usual to speak of it as an inexact science; this is obviously wrong, since medicine uses the same methods as every other science and the results of observation are as definite as those of the chemist or physicist, although it is true that in the complexity of the problem with which the physician may have to deal all the conditions of importance may not be known and the results of an investigation, though correct for the conditions under which it is undertaken, may be misleading.

It is not to medicine as a whole that I wish to direct attention here, but only to that part of physiology which forms the basis of treatment.

When the sciences of physiology and pathology a century ago passed from the realms of natural history to deduction and experiment, they naturally attracted the more original and eager minds in medicine, and the text of the writings of the nineteenth century deals with changes in structure and function. Treatment became neglected, the old shibboleths and rituals of treatment which had held sway for centuries were discarded, and there was nothing with which to replace them. Diagnosis was then and is now far ahead of treatment; diagnosis is often accurate where there is no satisfactory treatment, and yet diagnosis is only a means to the end.

The science of treatment or pharmacology is therefore relatively new; it includes knowledge of all kinds dealing with the treatment of disease or alleviation of suffering. It is the climax of physiology and pathology, devised to subserve a practical end, and forms an important part of the great biological topic of the influence of conditions on the living organism. Few drugs now exist the mode of action of which is not understood, and the goal is not so far distant when it will be possible to introduce into the animal economy a factor which will exaggerate or retard the function of any tissue or collection of cells in the body, leaving the others unaffected; and most of these results have been obtained by the methods used in experimental physiology.

The first object of science is to ascertain facts. Certain facts in physiology are relatively easily ascertained—those, for example, which involve the behaviour of ferments of isolated cells or of tissues, and require well-known chemical or physical methods. Other facts involving the physiology of the whole organism are more difficult to interpret, though they are the basis of the therapeutic side of medicine. More and more is physiology being regarded as the application of physics and chemistry to the phenomena of life. I might go beyond this and say that physiology is getting further and further from practical medicine, and this is the more regrettable as most of the chairs in physiology are connected with the medical schools and because the science of treatment is largely dependent on experimental physiology.

No branch of experimental biology has received less consideration in Great Britain than that of pharmacology: it is also the most neglected branch of medicine, and although the object of medicine is the healing of the sick, it is amazing that medical schools in Britain, often equipped with all other modern laboratories, lack departments of therapeutics. But the advent of institutions for experimental therapeutics is upon us, though Britain has taken little part in the movement. In this connexion we welcome the magnificent buildings of the University of Cape Town, and when the new hospital with its medical school is completed I confidently anticipate that adequate accommodation will be provided for that important branch of applied physiology, pharmacology, and that this will include laboratories of physiology and organic chemistry, which must be in close and direct association with the wards. The enormous importance of one branch of treatment to Africa, chemo-therapy, I will refer to later.

It is not surprising that British pharmacology should be so much behind that of other countries in the production of new curative remedies; practically all come from abroad; I may mention ephedrine for spasmodic asthma, liver extract for pernicious anæmia, insulin, the organic arsenicals, the dyes such as 205, the new anæsthetics local and general, hypnotics, and many others.

It has often been stated that the action of remedies may be best determined by experimenting with them on healthy men. This is not true; quinine is used to treat malaria, yet not one of the subjective symptoms induced in man has the remotest connexion with its curative properties. The same is true of the use of the iodides in syphilis and salicylates in rheumatism. The experiments of Joig and his pupils in 1825 with camphor, digitalis, and other drugs on healthy men added nothing of value to pharmacology. Subjective sensations are, it is true, produced, which are erroneously attributed to the drug which has been taken. Few,

[1] From the presidential address to Section I (Physiology) of the British Association, delivered at Cape Town on July 24.

if any, experiments made on man without the most careful controls are of any real value. Properly controlled experiments have been made, however, with many substances. Precise experiments, for example, have been made both in Germany and America with bromides in epilepsy. In these experiments half the epileptics were given potassium chloride and the other half sodium bromide; after several weeks' use the bromide had decreased the number of attacks, whilst the chloride had no distinct action.

Chemo-Therapy.

At one time hopes ran high that the chemical structure of the molecule might indicate pharmacological action. During the last fifty years, many laborious researches have been conducted with this object: to modify the molecule that it may conform to some required action. But the mystery remains as mighty as ever. It is most probable that subtle energy factors binding the molecule—factors not displayed in a formula—control the action; certain it is that drug action is not determined directly by chemical combination with body constituents, but rather by delicate physical processes such as those of adsorption, solution, and surface tension.

Chemists have as yet not even determined the requirements of the molecule for the production of colour sensation. On the other hand, slight alteration of a molecule already complicated and with a known action has led to the production of many useful compounds, and not infrequently we may foresee the type of action which will occur under such special conditions. Considerations of this nature have led to the synthesis of the new local anæsthetics, antiseptics, antipyretics, diuretics, tropeines, and other useful substances.

Parasites causing disease in man may be crudely divided into worms, protozoa, and bacteria. Chemotherapy, that is, specific therapy of infectious disease, has had marked success in curing disease due to parasites in the first and second of these groups; these diseases are found mainly in the tropics. It has obtained much less success in the third group.

Diseases due to protozoa have an especial significance in Africa, and reference must be made to that area of tropical Africa occupying more than a million square miles in which one form of these, namely, trypanosomes, produce their ravages. Trypanosomiasis is one of the most serious of all tropical diseases and affects both man and beast; it is a scourge which renders vast tracts of land practically uninhabitable and takes its death-toll often in thousands and occasionally even in hundreds of thousands, and yet it is a disease which I believe should be curable if not preventable. The problem is one of wide interest and importance—scientific, humanitarian, and economic.

The members of two groups of chemical substances excel all others in their curative value in trypanosomiasis and spirochætosis; these are the organic arsenical compounds and the dyes. The most satisfactory arsenic compound yet discovered for the cure of trypanosomiasis is tryparsamide. It is less toxic than atoxyl and has a slightly higher therapeutic index; it has a most marked trypanocidal action in animals and has been used with some success in cases of sleeping sickness from *T. Gambiense*. One injection causes the disappearance of the parasite from the blood of man, and if the injections are repeated in courses, the cure may be complete.

Dyes.

Many dye substances have been used in medicine. Trypan red and trypan blue belong to this group. Trypan blue was employed by my colleague, Prof. Nuttall, in piroplasma infections in animals, with results that most South Africans are well acquainted with. Afridol violet, a derivative of diamino diphenyl urea, and some allied dyes have also a powerful action on piroplasma.

How these substances act is not known, for like the organic arsenicals they do not kill the parasite *in vitro*. They have the property, however, of being adsorbed to the blepharoplast of the trypanosome; this adsorption is associated with diminished virulence of the parasite in infected animals, and after successive inoculations through several animals the organ may disappear. This direct action of a drug on a tissue, causing ultimately the complete disappearance of that tissue, is so remarkable that it is worthy of notice, as it represents the first known action of the kind.

The most valuable member of the afridol violet group so far produced was first made in the Bayer laboratory, but its composition was kept secret. It was, however, afterwards synthesised and its formula published by Fourneau, but only after long trials and infinite patience. The chemo-therapeutic index of this substance has the remarkable figure of 200 to 300; and so little as 1/32 mgm. will sometimes cure mice infected with trypanosomes. Fourneau has made many allied substances and derivatives of "205", he has modified the wings of the molecule by the addition of various side-chains, sometimes keeping the wings identical and sometimes changing them by joining two different complexes through the agency of phosgene. The number of such derivatives is obviously legion, and this makes it the more remarkable that he should have succeeded in synthesising "307", which at the present time is superior as a therapeutic agent to all other dyes in trypanosomiasis.

This "307" has a remarkable action on trypanosomes in laboratory animals, being three hundred times more effective than atoxyl. Its discovery has also opened a new era in therapeutics, since it represents the first chemical substance which when administered to man or animals in an infected trypanosome district gives a complete immunity to the disease for several months: it does not necessarily prevent trypanosome infection, but it prevents the effects of the disease. There is much in these experiments that suggests that we are on the fringe of a new pathology, and that our present crude methods of preparing anti-bodies in the future will be replaced by those of the organic and colloid chemist.

Bacterial Infections.

Tuberculosis is another problem of vast importance in South Africa, not only on account of its prevalence amongst susceptible individuals in both the European and native populations, but also because of its association with certain industrial diseases.

Much the most important industrial disease in South Africa is the silicosis produced in the extraction of gold from the conglomerate, both the pebbles and the matrix consisting of quartz. The gravity of pneumoconiosis depends largely on superadded tuberculous infection to which the workers have a predisposition, and in this respect crystalline silica is much more harmful than either amorphous silica or carbon. It may act by direct irritation, by its poisonous properties after solution, by colloidal action, or because it forms locally a nidus suitable for the growth of the tubercle bacillus.

Drugs are employed in tuberculosis either with the object of attacking and preventing the growth of the tubercle bacillus or other organisms with which the disease may be associated, of neutralising poisonous toxins, or of removing or relieving symptoms. It is with the first group that I am now concerned. Two groups of organic compounds are especially remarkable for their chemo-therapeutic action on bacteria. The first group has the quinine complex ; quinine is the methyl-ester of cupreine and it can be reduced by nascent hydrogen to form hydrocupreine. The following table shows the effect of two derivatives of hydrocupreine in arresting the growth of certain micro-organisms :

	Ethyl hydrocupreine (optoquin).	Iso-octyl hydrocupreine (vuzin).
Diphtheria bacillus .	1 in 100,000	1 in 750,000
Pneumococcus . .	1 in 400,000	Negligible
Staphylococcus . .	1 in 500	1 in 16,000
Streptococcus . . .	1 in 1,000	1 in 80,000

The action of optoquin on the pneumococcus and of vuzin on bacillus diphtheriæ is highly specific ; the higher and lower homologues have a greatly diminished effect. Many substances destroy bacteria in the test tube, but these drugs act in the animal body as well as in the test tube, and enough can be given by medicinal doses to animals and men to render the blood of these animals bactericidal.

The second group of drugs which exert a marked action on bacteria are certain derivatives of acridine. Trypaflavin was used during the War for infected wounds : unlike most antiseptics, it acts better in the presence of protein, but is not sufficiently selective or specific on micro-organisms in the presence of body tissues to be of any real value ; it is easily absorbed and readily causes œdema. Rivanol is a more recent derivative of acridine. Morgenroth cured streptococcic infections by injections of rivanol under the skin. The injections to be efficient must be made soon after the infection and in the neighbourhood of the inoculated zone ; rivanol will not cure a blood infection. The destruction of the tubercle bacillus presents two special difficulties : first in the fatty and protective envelope surrounding the bacillus, and second in the small blood supply to the tuberculous lesion.

Hoyle and I have recently investigated two new types of gold compounds in tuberculosis. One of these is a complex aurous salt of ethylenethiocarbamide with the formula $(Au,2etu)H_2O$, where ' etu ' represents ethylenethiocarbamide.

This compound, prepared by G. T. Morgan, is stable, crystalline, and colourless at ordinary temperatures. It is soluble in distilled water, forming a solution neutral to litmus and with a pH value of about 6·2. It was tested for therapeutic effects on both human and bovine types of infection. For the former, inoculations were made subcutaneously into guinea-pigs with 1 mgm. doses of a virulent human strain. All the animals, control and experimental groups, died within a few weeks of one another, and all showed characteristic progressive lesions of similar extent.

It was found that treatment with the gold compound in bovine disease in rabbits prolonged life about 50 per cent when compared with controls. We adopted the arbitrary standard that treated animals should survive at least two or three times longer than the average length of life of the controls before clinical trial should be proceeded with. In view of the wide variations in individual susceptibility, and the difficulty that this entails in drawing sound positive conclusions from a small series of animals, it is absolutely necessary to exercise the utmost caution before arousing clinical expectations.

The second compound tested by us was a complex gold derivative of succinimide, prepared by my colleague, Sir William Pope. This compound is non-ionised and the gold is associated in chemical combination in an internal organic ring. It is a white, crystalline, stable compound at ordinary temperatures, readily soluble in water to a neutral solution.

This substance was tested for therapeutic effect in experimental bovine infections in rabbits. In some animals this treatment was supplemented by injections of potassium iodide subcutaneously ; in no case has any therapeutic benefit been observed. There has been no increase in the lengths of life of the treated animals, and the type and extent of disease at post-mortem examination in treated and control animals has in every case up to the present been similar.

These compounds are interesting because one delays death and the other is entirely without action. They may afford a hint as to the lines on which organic chemists should proceed, and perhaps show that gold in the ionic form is desirable.

The Internal Secretions.

In the last twenty years much evidence has accumulated to show that the glands of internal secretion are responsible for the regulation of growth, of metabolism, and often for our appearance if not for our very character. Exaggeration or diminution in the secretion of one or other of the tissues may induce conditions so decided as to be obvious to everybody, though the effects produced by minor alterations in the co-ordination of the several

secretions may not be so evident. Giants and dwarfs, unusual pigmentation and anæmia, disproportion in the growth of the skeleton, such as enlarged hands and face, bulging deer-like eyes or oriental eyes and beards in women are noticeable to everyone ; excessive fatness or emaciation, a choleric or bucolic temperament cause no comment, yet may equally arise in the victim from a want of co-ordination in the internal secretion.

The gonads present the clearest evidence of the influence which a tissue may exert on metabolism. I will refer only to the ovary. The ovary differs from other organs of internal secretion in that it functions in a cyclic manner, and it is obvious that extracts made from ovarian tissue may exert a different action according to the period of the cycle when they are made. Numerous extracts have been prepared from the ovary which are reputed to exert one or other type of action. ' Oestrin ' is the name given to one such substance : it can be made from many sources, both animal and vegetable, besides the ovary. Oestrin exerts a very definite action in lower animals, but its use in man is so variable and disappointing as to make it valueless in practical medicine. When it is injected subcutaneously into spayed rats and mice it produces typical oestrus with normal sex instincts, and when injected into immature animals it induces puberty ; regular injections at fixed intervals will keep animals sterile.

Many experimental observations show that the corpus luteum is concerned with the rhythm of the oestrus cycle and with the prevention of ovulation. A persistent corpus luteum, both in the case of animals and women, produces sterility, a condition which is cured by its removal.

A third active substance distinct from oestrin and corpus luteum is elaborated by the ovary and was described by Marshall and myself. This substance is water-soluble and thermo-stable, and can be prepared from the ovary at one stage of its cycle only, by maceration with warm saline followed by boiling and filtering. The injection of this substance into animals causes a secretion of pituitrin, and this in turn renders the uterus supersensitive and highly responsive to other forms of stimulation.

Our experiments showed that at one stage only of the ovarian cycle was this hormone elaborated, namely, at the stage when the corpora lutea are degenerating. So long as the corpora are functioning they control the metabolism of the ovary, but when they degenerate control is lost and the ovary liberates the specific substance which excites the pituitary gland to secrete. This means that extracts of the ovary made between the heat periods or during pregnancy are without effect on the pituitary gland, but extracts made just before the heat period or just before parturition induce secretion of the gland. As the significant action of pituitary extract is to sensitise the uterus it is difficult, if not impossible, to avoid the conclusion that these two phenomena are closely associated.

It is not suggested that the ovario-pituitary endocrine mechanism is the sole factor in producing labour pains. No doubt the fœtus itself acts as a direct stimulus, and without the fœtus the intense muscular contractions would not occur, but it is also clear that the onset of labour cannot easily be accounted for without postulating some further exciting cause apart from the fœtus and the uterus.

In conclusion, no romance can be more remarkable than the fact that doctors, by using pituitary extract to stimulate the uterus in pregnancy, should have adopted the method which Nature herself employs and that physiological function is after all a pharmacological action.

Medicine and Physiology.

Civilisation has been responsible for many new diseases. Our food-stuffs in great cities are often preserved and important constituents of fresh foods may be lacking. The science of dietetics has assumed an enhanced importance lately, which is partly due to the artificial preparation of many of our foods. Many experiments have been made in my laboratory to show that certain foods given in excess to animals fed on a synthetic diet, but containing an ample supply of the recognised vitamins, suffer from poisoning sometimes of the most profound and fatal kind. The same experiments made on animals living on an ordinary diet show that the excess of the ' poisonous ' food is harmless. For example, certain preparations of irradiated ergosterol given to rats which are being fed on a synthetic diet act as a poison, but if the rats are fed on bread and milk the effect of the ergosterol is negligible. In real life we do not live on a completely synthetic diet ; nearly everyone takes some if not an abundance of fresh food, so the practical value of this type of experiment may be over-estimated, though it is of considerable academical interest.

Civilisation has brought bad sanitation in houses, and even our windows may be depriving us of fresh air and filtering out certain rays of light, bringing its attendant tuberculosis—for tuberculosis is a disease of houses. Science is now engaged in endeavouring to remedy the evil effects which it has produced.

I have endeavoured to show that all precise knowledge in therapeutics is based upon controlled experiments on animals or man, and that the elucidation of the action of medicaments by the methods and data of experimental physiology is one of the most important steps taken to place medicine on a scientific basis. How important this is may be gauged from the fact that all fundamental advances in treatment in the last thirty years have originated directly or indirectly from experiments on animals. There can be no doubt that the future of therapeutics, and therefore of medicine as a whole, is intimately connected with physiology.

Britain for fifty years has every reason to be proud of her progress and achievements in physiology ; it is acknowledged that she can show records second to none and that her savants have included some of the world's greatest investigators. It remains for us to hope that in the future she may attain equal success in the associated sciences directly concerned with the relief of suffering and cure of disease.

News and Views.

IN staging joint discussions upon various subjects of general interest, the British Association performs one of the most useful of its public functions. Scientific workers of different schools and training meet, as they seldom do, to focus their peculiar outlooks upon a particular problem; the public benefits by hearing at first hand the latest developments of scientific thought or discovery, and can scarcely but be impressed by divergences of opinion which suggest that science, still in process of development, abhors dogma and finality. The discussion on "The Nature of Life", held at Cape Town on July 25, was more than usually interesting, since it indicated a swing of the pendulum towards the vitalistic view of the nature of life. According to the Cape Town correspondent of the *Times*, General J. C. Smuts, in opening the discussion, developed his theory of 'holism', which he regards as avoiding the difficulties of both the vitalistic and mechanistic theories. Life is neither a substance nor a force; it is a structure, a new emergent structure based on pre-existent physical structures. Evolution from the most primordial forms of matter to the highest forms of mind is a continuous process, and this process is characterised at one end by physical structures with a minimum of functional structure, and at the other end by functional structures with a minimum of physical structure, and in between by a transition area of combined physical and functional structures. The first is called matter, the second mind, and the area of mixed structures, life.

LIFE-STRUCTURES or patterns, according to General Smuts, have the characters of wholes, which are not mechanical aggregates, but in which each part influences and moulds every other part. In a whole, the parts are really members, and the whole itself appears to play a centralising, unifying, and co-ordinating rôle. Dr. J. S. Haldane in general agreed with General Smuts's rejection of orthodox vitalism and mechanism, and accepted the holistic view of life as a unity which maintains and asserts itself in an environment which is part of its whole. Prof. Wildon Carr stood for the vitalistic outlook, and suggested that Smuts's holism is but another name for entelechy, and that the reality of life is activity of an essentially individual and purposive nature distinct from mechanical activity. Prof. L. Hogben said that he is not prepared to believe anything not amenable to experiment; Prof. A. S. Eddington pointed out that the essential requirements of holism are not radically inconsistent with the mechanistic hypothesis; and Prof. G. Barger made striking testimony to the failure of synthetic chemistry to build up a living cell, pointing out at the same time that although the mechanistic view is difficult to accept, resort to other hypotheses seems to be treachery to science.

ON July 23 the Institution of Professional Civil Servants gave evidence before the Treasury Committee, presided over by Sir Harold Carpenter, which is examining the method of recruitment and conditions of service of the civilian scientific and technical officers employed in Government Departments. At the request of the Committee the Institution had previously prepared a preliminary statement of evidence indicative of its general policy in regard to the matters which the Committee is charged to examine. The Institution's witnesses were led by its president, Sir Richard Redmayne, who was supported by Messrs. S. H. Bales, T. Smith, R. A. Watson Watt, and C. L. Leese. As the Institution is representative of all classes of scientific workers employed by the State in the departments under consideration by the Committee and has acted in consultation with the Association of Scientific Workers, its views upon the organisation of the scientific departments and the conditions upon which the staffs should be employed are worthy of full consideration. The Institution submitted proposals for the co-ordination of all branches of scientific research and experiment in a unified State scientific service. Such a service would involve a common system of recruitment, promotion, and conditions of appointment, and uniform scales of salary. The Institution also emphasised the need for appropriate salary scales and status for scientific officers in order to attract suitably qualified candidates. The careers offered to the scientific staffs should be equal to those offered to their professional and administrative colleagues.

THE Institution submitted specific proposals for common grading and salary scales for a scientific service which in its view could be applied to scientific organisations as at present constituted. It considered that the basic grade should normally be recruited from candidates between the ages of 21 and 24 years who possess an honours degree of a British university or its equivalent. Confirmation in the grade should be subject to the issue of a certificate of competence to perform the full duties of the grade, and such certificate should only be issued after a period of two years of strict probation. The Institution has followed the precedent established in the museums, Royal Botanic Gardens, Kew, and the Patent Office, in submitting a long scale for the basic grade in order that men who perform good service but do not possess such exceptional ability as to obtain promotion quickly shall be in a position to educate their children appropriately and to retire on an adequate pension. The Institution considers that provision for special promotion should be made for officers of exceptional ability. The Institution also dealt with the pay at present attaching to the highest posts in the scientific departments, which it considers entirely inappropriate to the status and responsibilities of their occupants.

THE sixty-eighth annual meeting of the Devonshire Association and the summer meeting of the Newcomen Society were held together at Dartmouth on July 23–26. While both societies carried out their own usual programmes of visits, etc., they joined together to commemorate the bicentenary of the death of the great inventor, Thomas Newcomen, who was born at Dartmouth in 1663 and died in London on Aug. 5, 1729. In the absence of the Mayor of Dartmouth through illness, the members of the Societies

were officially welcomed by Alderman Pillar on behalf of the Corporation of Dartmouth, after which a eulogy on the work of Newcomen was pronounced in the public gardens at the site of the Newcomen memorial by Mr. L. St. L. Pendred, president of the Newcomen Society. Speaking of Newcomen as a man who had brought fame to his town, his county, and his country, and had given the whole world the art of converting fuel into useful power for the benefit and convenience of humanity, Mr. Pendred referred to the difficulty of visualising the conditions with which Newcomen had to contend. Acquainted with the needs of the mines of Cornwall and Devon, which were being killed by the influx of water with which the antique pumping plant of the day was unable to cope, it was Newcomen's glory that he, and he alone, saw the means of meeting the needs and that he produced a design so perfect in its simplicity that for many a long day no radical improvement in it was effected and no other engine appeared in opposition to it. Knowing little of the man himself, yet we may suspect that he had some of the "Divine insanity of noble minds that never falters or abates, but labours, and endures, and waits, till all that it foresees it finds, or what it cannot find, creates".

THE last of the joint meetings was held in the Subscription Rooms at Dartmouth on July 25 to hear a lecture on "Thomas Newcomen—Two Hundred Years of Steam Power", by Eng. Capt. E. C. Smith. Capt. Smith said that though the steam machinery of to-day is the outcome of the work of hundreds of inventors, engineers, and men of science, there are four great landmarks in its history. The first of these is the introduction of the atmospheric steam engine by Newcomen, the second is connected with the epoch-making discoveries and inventions of Watt, the third is the adoption of the compound engine for ships, which we owe to John Elder, and the last is the invention of the steam turbine by Sir Charles Parsons. Historians often fail to realise the importance of the work of Newcomen, who began building engines sixty years before Watt. Watt's great improvements were made between 1765 and 1785, after which came the application of steam to transport on land and sea. Watt had nothing to do with this. The steam engine itself and the locomotive were purely British inventions, but the steamboat was largely due to work in America. By 1840 the total horse-power of the world's steam engines was about 2,000,000; by 1880 it was about 28,000,000; to-day it runs into hundreds of millions, and there seems no adequate reason to think that the steam engine will lose its place as the most important prime mover. Looking back to the days of its original introduction, one can say that Newcomen stood in relation to Watt very much as Trevithick stood in relation to Stephenson: Watt and Stephenson were the great improvers, Newcomen and Trevithick the original pioneers.

IMMEDIATE success has attended negotiations between the Australian Council for Scientific and Industrial Research and the University of Adelaide for the establishment of a Division of Soils Research for the Commonwealth. The Council recently invited the University to co-operate with it in this project, the broad division of responsibilities being that the latter should provide the required laboratories in the grounds of the Waite Agricultural Research Institute, and the former should provide equipment, staff, and maintenance and generally conduct the work of the Division. Within three weeks the University was able to announce that through the generosity of Mr. Harold Darling, acting on behalf of his family, which has for a long time been intimately associated with South Australian agriculture, the sum of £10,000 had been made available for the erection of the necessary laboratories. It is understood that Prof. J. A. Prescott, while still retaining his chair of agricultural chemistry in the University, will be the chief officer of the new Division. He has for some time been adviser on soils problems to the Council for Scientific and Industrial Research, and under his direction much useful work has been done on the soils of some of the irrigation areas. The new move will make possible a considerable extension of activity which, through the Imperial Bureau of Soil Science at Rothamsted, should ultimately benefit many other parts of the Empire.

IN connexion with Mr. Field's suggestion, referred to in our issue of July 27, p. 156, that some of the early peoples of North Arabia may have moved into the Nile Valley, we may refer to a letter from Mr. Guy Brunton which appeared in the *Times* of July 18, in which he gives extracts from a report presented to the Trustees of the British Museum, describing further excavations in Egypt bearing upon the origin and affinities of the Badarian culture. Some doubt has been expressed as to the early date of this culture, but in the past season a widespread Badarian settlement deposit was found into which were sunk many graves clearly subsequent and typically early pre-dynastic (Amratian). The relation between Badarian and Amratian was clearly indicated by the discovery of intermediate types of pottery. An Amratian flint knife 17 inches long is perhaps the longest known. An important addition to our knowledge of the earliest predynastic civilisation has been made in the confirmation of the early date of the culture to which the name Tasian has been given. This culture differs from the Badarian; its pottery, while akin to the Badarian, is distinct and thought to be of earlier date. This is now confirmed by the investigations of Dr. Sami Gabra near Deir Tasa, where an undisturbed grave was found to contain a typical pot and two stone celts. This people apparently also used incised beaker-shaped vases of black pottery. Three skulls have been found in good condition. They differ in type from Badarian, being rounder headed, with squarish faces and heavy square jaws.

IN the same issue of the *Times* is a further contribution to Egyptology, which is also of interest to Biblical students. Dr. A. M. Blackman, in a lecture at Oxford, has suggested that the Papyrus Salt may refer to Moses. An incident described in that papyrus states that the punishment inflicted upon a workman for his misdemeanours by a vizir was revoked by 'Mose'. Apparently he was influential enough to secure the deposition of the vizir, though no title is given him and

no mention is made of any official position held by him. Dr. Blackman suggests that this casual introduction of his name may point to the fact that he was well known as a redresser of grievances interested in the workman class as we know Moses to have been. If this highly speculative suggestion could be supported, it would be of no little interest. It has, in addition, an important bearing upon another point. If the identification were accepted, it would place Moses' sojourn in Midian as during the last years of Sethos II. At the death of this Pharoah five troubled years followed which would have afforded a favourable opportunity for the Exodus. This would give a date for that event at most fifteen years later than the death of Meneptah, in whose reign it is placed by generally accepted chronology, but whose strong character is scarcely consistent with the course of events of the Biblical narrative.

According to the British Rainfall Organisation, Meteorological Office, Air Ministry, the total rainfall over Great Britain for the six months, January to June 1929, was less than 70 per cent of the average for the same period almost everywhere, the only important exceptions being the counties of Devon, Cornwall, and Pembroke, parts of the south-western isles of Scotland and of an adjoining strip on the mainland, a narrow belt along the east coast of Scotland, an area in north-east Yorkshire, and a part of Sussex and the Isle of Wight. In spite of a June which was generally wet in Scotland, percentage values of less than 50 per cent for the six months were recorded in Ross and Cromarty. Another area of less than 50 per cent included a part of south Yorkshire and the northern portions of Derbyshire and Nottinghamshire. At Camden Square, London, the total fall for the six months was 52 per cent of the average. In Ireland the fall for the six months was generally in excess of 50 per cent. Less than 60 per cent occurred along the north-west coast and around the mouth of the Shannon. More than 80 per cent occurred in places on the east coast, while the highest percentage value for the six months was 116 per cent at Waterford. In most parts of England, Wales, and Ireland, June was a dry or very dry month. Only about 40 per cent of the June average was recorded in the southern Pennine area, in the eastern parts of Lincolnshire and Norfolk, in a large area including much of Cambridge, Bedford, Hertford, and Essex, and round the mouth of the Shannon. More than 180 per cent of the average June fall was measured in the extreme north of Scotland and more than 130 per cent in the extreme north of Ireland. About 150 per cent of the average amount fell in south-west Cornwall. At Camden Square, London, the June fall was 64 per cent of the average.

Several specimens of the Nkosi Island situtunga (*Limnotragus spekei sylvestris*), recently described by Colonel R. Meinertzhagen, have been received in the Department of Zoology of the British Museum (Natural History) from Captain C. R. S. Pitman, Game Warden of Uganda. Nkosi Island, the southernmost of the Sesse Group, in the Victoria Nyanza, is an island covered with dense, dry forest, and the situtungas, which are usually swamp-dwelling antelopes, have assumed more terrestrial habits. Colonel Meinertzhagen estimated that in 1926 there must have been at least two hundred of these animals existing on Nkosi Island. The Department of Entomology of the Museum has received from Mr. F. W. Urich, Port of Spain, Trinidad, six examples of *Pantophthalmus tabaninus* Thunb., a large two-winged fly, specimens of which sometimes measure as much as two inches in length. *Pantophthalmus*, which occurs in the West Indies and other parts of tropical America, is the largest of all Diptera; notwithstanding its formidable appearance, however, it is quite harmless and is incapable of biting. The larvæ have the remarkable habit, unique among Diptera, of boring in the solid wood of living trees, in which they gouge out clean-cut, nearly horizontal tunnels, and feed upon the exuding sap. Mr. Frank H. Taylor has presented a green cicada (*Cystosoma saundersi* Westw.), taken by him at Eungella, Queensland. The song of this insect, which in New South Wales and Queensland occurs locally in vast numbers, is heard in hot and sultry weather before a thunder-storm. It is said to be unlike the shriller and harsher notes uttered by the common cicada, and to resemble the sound of a loud, deep, and guttural 'R', continued incessantly, with vibrations. The Trustees have accepted for the Department of Botany the bequest by the late Mr. Arthur Bennett of his herbarium of British pondweeds. Mr. Bennett made a lifelong study of the genus *Potamogeton*, and the value of his herbarium is much enhanced by the inclusion of numerous notes and correspondence relating to the specimens.

At the eighth annual general meeting of fellows of the National Institute of Agricultural Botany at Cambridge on July 26, the chairman of the Council, Dr. E. S. Beaven, reviewed in turn the principal activities of the Institute in the past year. Two important branches of the work, the Official Seed Testing Station, and the Wart Disease of Potatoes Immunity Trials, are delegated to the Institute by the Ministry of Agriculture, and these functions are supplemented by cognate investigations into germination problems, potato virus diseases, and the yield and maturity of potato varieties. The Potato Synonym Committee, of which Dr. Salaman is the chairman, has reported a substantial improvement in the nomenclature of potatoes; the Council hopes to win the co-operation of seedsmen in extending this work to cereals. Dr. Beaven referred to the encouragement offered in the last century by the Royal Agricultural Society to plant-breeders and, after tracing the relationship between animal and plant breeding and the influence of Mendel's work, pointed out that field trials of the kind undertaken by the Institute would be needed for many years. The difficulty of the task and the value of the results were illustrated by the series of barley trials completed in the past year. Two varieties raised by systematic methods of plant breeding were shown to be generally and significantly more profitable to farmers than any others, and records collected

independently by the Official Seed Testing Station and the Essex County Farmers Union not only confirmed this conclusion but also showed that these two varieties are now grown more widely than any others. The study by competent critics of these and the similar results now being obtained at the Institute should win for it the support of agriculturists.

WE learn from the *Times* of July 23 that at the suggestion of Dr. R. J. Renison, rector of Christ Church, Vancouver, the Royal Empire Society is having a plaque made in England to be placed in Vancouver Cathedral to commemorate the work of Captain Cook in that part of the world. Records show that it was in 1778 Cook sailed up the west coast of North America. He struck the coast at Lat. 44° 55′ N. on Mar. 7, and he "proceeded to make an almost continuous survey of the coast" up to and beyond Bering Straits as far as Lat. 70° 41′ N., where he was barred by the ice. He named the farthest visible point, Icy Cape; he also discovered and named Nootka Sound, Prince William's Sound, and Cape Prince of Wales; and he penetrated Cook's Inlet. His work is believed to have inspired that of Vancouver in 1792, when the latter circumnavigated the island that now bears his name. The memorial is to be unveiled in September during the visit of Sir John Sandeman Allen, chairman of the Royal Empire Society.

MR. F. W. SKINNER, in *Engineering* for July 19, gives an account of the difficult, but finally successful work, of righting one of the large reinforced concrete caissons which had capsized on July 27, 1927, while being sunk into position for one of the piers of the Poughkeepsie Suspension Bridge, N.Y. The caisson, 136 ft. long, 60 ft. wide, 104 ft. high, when it capsized, had a weight submerged of nearly 13,000 tons, equivalent to about 19,000 tons in air. Owing to the great depth of water, strong tidal currents, formation of ice, and the traffic in the river, the work of righting proved an arduous matter, and it was not until Oct. 8, 1928, that the caisson was finally in position again. The methods employed included the weighting of the higher side of the caisson, lifting the lower side by means of steel pontoons from which the water had been pumped, and pulling by tackles anchored in the river bed. It was estimated that forces approximating to 100,000 ft.-tons were brought to bear on the caisson as against the adverse moment of 40,000 ft.-tons. After righting, the sinking operations were resumed and the pier completed on May 17, 1929.

WATCHING the modern passenger-carrying aeroplane in the air, it is difficult to realise that a machine built just over twenty years ago is of sufficient interest and importance to justify a place in the Science Museum, Kensington. So fast has been the progress of aeroplane construction, however, that the little monoplane in which M. Louis Blériot crossed the English Channel on July 25, 1909, is now a historic relic. The occasion was commemorated on Saturday last, when M. Blériot crossed the Channel in one of his latest machines, a twin-engine monoplane of about 1000 h.p. The crossing occupied 12 min., as against the 33 min. taken in the flimsy little machine he used twenty years ago. M. Blériot landed at Swingate Aerodrome, Dover, and went by motor-car to North Foreland Meadow, where there is a commemoration stone to mark his landing there in 1909. He was welcomed by the Mayor of Dover and Sir Sefton Brancker, Director of Civil Aviation in Great Britain, and afterwards proceeded by air to London. The same evening, M. and Mme. Blériot were the guests of honour at a dinner, presided over by Lord Thomson, Secretary of State for Air, to celebrate the Seventh International Aero Exhibition being held at Olympia.

A CONSIDERABLE earthquake was recorded at Kew Observatory on July 23. The first impulse reached the Observatory at 8 hr. 47 min. 5 sec. Greenwich Mean Time. The seismograms indicate that the epicentre was close to the north coast of Ireland.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned :—A lecturer in mechanical engineering at the Swansea Municipal Technical College—The Director of Education, Education Office, Dynevor Place, Swansea (Aug. 10). Inspectors for the purposes of the Diseases of Animals Acts, 1894–1925, under the Ministry of Agriculture and Fisheries—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall-place, S.W.1. (Aug. 12). A technical officer, at the Royal Aircraft Establishment, for writing descriptive matter and instructional handbooks on wireless and electrical apparatus—The Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants (Aug. 13). An assistant in the dairy bacteriology research division of the Ministry of Agriculture for Northern Ireland—The Secretary, Civil Service Commission, 15 Donegall Square West, Belfast (Aug. 14). A taxidermist and an assistant librarian in the Faculty of Science of the Egyptian University, Cairo—The Director of the Egyptian Education Office, 39 Victoria Street, S.W.1 (Aug. 15). A resident lecturer in geography at the Caerleon Training College for Men—C. Dauncey, County Hall, Newport, Mon. (Aug. 21). An assistant lecturer in physics at the Bradford Technical College—The Principal, Technical College, Bradford (Aug. 23). A chemist with experience in research on yeast problems for research work in industrial microbiological chemistry—The Research Manager, Imperial Chemical Industries, Ltd., Technical Department (Nobel Section), Stevenston, Ayrshire. A lecturer in physics at the Memorial University College, St. John's, Newfoundland—S. T. Harrington, Woodfield, Malvern Wells, Worcs. Laboratory assistants at the Royal Arsenal, Woolwich—The War Department Chemist, B.47, Royal Arsenal, Woolwich, S.E.18. A computer under the Government of Tanganyika Territory, for the Survey Department—The Crown Agents for the Colonies, 4 Millbank, S.W.1 (quoting M/1405). A junior assistant in the department of the War Department Chemist—The War Department Chemist, B.47, Royal Arsenal, Woolwich, S.E.18. A lecturer in agricultural chemistry in the University of Reading—The Registrar, The University, Reading.

Research Items.

Salmon Fishery in California.—The development of the use of water-power in Great Britain and its preliminary, the impounding of lakes and damming of rivers, are bound ultimately to have an adverse effect on the salmon productivity of the country, and that probably in spite of the best safeguards which can be agreed upon. The lesson of the Sacramento and San Joaquin Rivers in California, the first rivers there to to be fished for salmon by white men, is a plain one. Since 1874 the fishery has produced 205 millions of pounds of salmon (says *California Fish and Game* for January), and now, in an endeavour to keep up the stock, as many as 100,000,000 young salmon from hatcheries have been planted in a single year. Overfishing is apparently one cause of the decline, but a factor, scarcely less important, is the cutting off of the spawning grounds by dams. An important investigation of the spawning beds has just been completed, and this has necessitated observations of obstructions in the streams and of the workings of fish-ladders and screens. The survey has determined that, as near as can be calculated, there were, in 1928, 510 lineal miles of stream in which salmon might spawn, as compared with the 6000 miles before the dams were constructed. It is estimated that 80 per cent of the spawning grounds in the Sacramento and San Joaquin river systems have been cut off by the obstructions of dams, both power and irrigation. The salmon fishery in California is now at the point when something must be done, and at once, in order that it may be preserved for future generations to enjoy.

An Amphibious Centipede from India.—At the Indian Science Congress, B. Bonnell described the finding of a Geophilid in loose soft mud in the mouth of the Coum River, Madras. The specimens were obtained in July 1928 when collecting polychæte worms, *Marphysa* and *Lycastis*, in the bed of the river in brackish water. It was found that the centipedes could withstand immersion in water for nearly twenty-four hours. The other amphibious centipedes recorded are *Linotenia maritima* and *Schendyla submarina* on the shores of the Mediterranean and on the Atlantic coast of Europe, and *Pectiniunguis americanus* under seaweed, driftwood, etc., on the shores of the Gulf of Mexico. The author suggests that amphibious centipedes may be more widely distributed than these records indicate.

The Mammals of Ceylon.—Since a provisional list of the mammals of Ceylon was published in 1923, many new forms have been discovered in the island, and new facts have been brought to light regarding distribution. Accordingly W. W. A. Phillips contributes a new check list, in which the names, scientific and native, and the range of each species and subspecies are recorded (*Spolia Zeylanica*, vol. 15, p. 119; 1929). The mammals have increased in number to ninety-eight species and sub-species, and even the bare list brings out some interesting features. Ceylon may be broadly divided into three climatic zones, the low-country dry zone, comprising the northern half of the island and possessing a fauna closely resembling that of the Indian mainland; a low-country wet zone; and a central hill zone. Each zone has a fauna differing in many respects from that of each other zone, and in many cases the forms found in any zone are peculiar to it and are not found in the remainder of the island.

Rhizopoda of the North Sea and Baltic.—Dr. L. Rhumbler (Die Tierwelt der Nord- und Ostsee. Lieferung 13, Teil II. a, "Amœbozoa et Reticulosa)" describes the Amœbozoa and the Foraminifera of these regions. Although marine amœbæ are very common they are still little known. It seems extraordinary that only one species has been described which was actually living in the North Sea, and this one is a parasite in the diatom *Biddulphia sinensis*. Free-living amœbæ have been found by Rhumbler and Gruber in aquaria filled with North Sea water—*Amœba comminuens* and *A. crystallina*—and in aquaria filled with Baltic water from Kiel six species, including *A. crystallina*, have been described. Three of these are well known in fresh water. Many of the small amœba-like organisms found in the sea are most probably phases in the life of certain Foraminifera. In the sub-order Testacea only five species are known in the sea water and these mostly from aquaria. Amongst them is the interesting *Trichosphaerium sieboldii*, which has an alternation of spore formation with a gamete-forming phase. On the other hand, the order Reticulosa is rich in species. The Foraminifera have always been specially studied. They are easily collected and the shells are varied and beautiful. Two species of the sub-order Nuda are included, and a member of the genus *Labyrinthula* not yet identified has been found commonly in the sea-water aquaria of Heligoland. All the rest belong to the true Foraminifera. There are useful keys for the identification of species, of which there are about 200 in the area, chiefly from the North Sea and western Baltic, the eastern part of the Baltic being poor in these little organisms.

Possible Molluscan Hosts for Cercariæ in the Shan States.—The occurrence of schistosomiasis in coolies from Yunnan at a hospital in the Northern Shan States, and the fear of the possibility of the spread of the disease from China into Burma, led to a survey of the molluscs of the Northern Shan States with the view of ascertaining if any known carriers occurred in the region. This survey was conducted in November 1926–January 1927, under the direction of Dr. H. S. Rao, of the Zoological Survey of India, and his report on "The Aquatic and Amphibious Molluscs of the Northern Shan States, Burma," has now been published (*Rec. Indian Mus.*, vol. 30, pt. 4). It is a very careful and thorough systematic account, admirably illustrated, of the 48 species of mollusca (including 29 forms, races, and varieties) met with, of which one genus, *Ekadanta*, and 21 species and forms of gastropods, are described as new. So far as the occurrence of schistosome cercariæ and of the known carrier-snails was concerned, the results of the survey were negative, but the adaptive, if not the specific host of *S. japonicum* occurs in the Shan States, and the constant stream of Chinese coolies which comes in from adjacent infected Chinese provinces is more likely than not to carry with it the insidious parasite. A thorough survey of the frontier districts at all seasons hence seems to be desirable.

Tropisms and Sense Organs of Lepidoptera.—Under the above title, Dr. N. E. McIndoo, of the U.S. Bureau of Entomology, has written an excellent illustrated article which appears as Smithsonian Miscellaneous Collections, vol. 81, No. 10 (1929). It is well known that many phases of insect behaviour are still unexplained and, in turn, behaviour is largely the result of tropic responses. In this paper Dr. McIndoo brings together the available information on the tropisms and sense organs of Lepidoptera, and includes the results of his own special studies on the

codling moth. Certain tests carried out with larvæ of this insect indicated that, when in the first instar, their eyes are photopositive and they search freely for food, but they are apparently not aided by their senses until within a few millimetres of the food. Larvæ in the fifth instar sometimes acted indifferently to light, but generally were weakly photonegative. Older larvæ when ready to spin their cocoons are strongly photonegative: they react positively to gravity and to thigmotropic stimuli, whereas the younger larvæ behaved in an opposite manner in relation to these three types of stimuli. Change in tropisms, therefore, brings about great differences of behaviour. The author believes that those sensory structures, termed by him 'olfactory pores', which are widely scattered on the bodies and appendages of both the moths and their larvae, are receptors of smell.

Proteolytic Enzymes in Green Malt.—The attempt to identify the proteolytic enzymes of plants with systems like the tryptic and peptic types of animals has been criticised by C. K. Mill and K. Linderstrøm-Lang (*Compt. Rend. Lab. Carlsberg.*, **17**, 1-14; 1929), who prefer to characterise the plant enzymes by the nature of the substances they affect. In green malt, for example, they distinguish only two enzymes of the proteolytic type, a protease (*p*H optimum 4·3) and a peptidase (*p*H optimum 7·6-7·9), the action of which on dipeptides is greatly inhibited by phosphates.

Ocean Surface-Water Temperatures.—Means of accurate and quick recording of surface temperatures of the ocean are described in a paper by Sir Frederic Stupart and Messrs J. Patterson and H. G. Smith in *Bulletin* No. 68 of the National Research Council (Washington, D.C.: National Academy of Sciences). The most effective instrument was found to be a mercury-in-steel thermograph in which the bulb was heavily plated with copper and inserted in the intake of the steamer's condenser. The recording part is of the usual thermograph pattern and is fixed between two ribs of the ship. The trace never showed any signs of vibration. The apparatus was tried on North Pacific and equatorial steamer routes. So far, the most numerous data have been obtained from the North Pacific. A study has been made of departures from normal of North Pacific water temperature, with the view of discovering if any correlation can be found between variations in water temperature and the weather of western Canada. A fairly definite correlation has been established, especially in winter, between the temperature of the water and the intensity of the Aleutian atmospheric low pressure area. When the temperature gradient is large the pressure is low, and this means increased oceanic winds with higher temperatures on the Canadian seaboard. However, when the temperature gradient of the water has its normal maximum in summer, the Aleutian low is not marked, so that other factors must be involved.

Superconductivity of Thorium.—The issue of *Die Naturwissenschaften* for May 24 contains a short note from Prof. W. Meissner, in which he states that he has succeeded in obtaining metallic thorium in the superconducting state. The specimen experimented upon was a single crystal, 12 mm. long and 3 mm. thick. When cooled in liquid helium its electrical resistance was at first a little less than two per cent of its resistance at 0° C. The transition took place at about 1·4° absolute, and at 1·3° absolute the resistance had fallen to less than 10^{-4} of its value at 0° C. Thorium becomes a superconductor at a lower temperature than any other metal which it has yet been found possible to obtain in this peculiar condition, the lowest transition temperature previously recorded being 2·1° absolute for the gold-bismuth eutectic. Prof. Meissner suggests, however, that silicon may become superconducting at some temperature below 1·2° absolute.

The Carbon Molecule.—Dr. R. C. Johnson and Mr. R. K. Asundi have contributed an interesting paper to the July number of the *Proceedings of the Royal Society* on the diatomic carbon molecule which exists in the discharge tube. Two years ago, before the guidance afforded by recent developments of the theory of band spectra had become available, Dr. Johnson had suggested, in connexion with an analysis of the fine structure of the well-known Swan bands, that these arose from a molecule with the same empirical formula as acetylene (C_2H_2). Since then, evidence, which is largely summarised in the present paper, has been accumulating that carbon (C_2) and not 'acetylene' is the true emitter, and this view is now endorsed. In addition, it has been found possible to extend the previously described so-called high-pressure bands of carbon into the ultra-violet and infra-red, and it has now been shown that both these and the Swan bands represent transitions to a common final state. Dr. Johnson also discusses the discharge conditions under which C_2 molecules are likely to be found, and states very clearly and with some extension Mulliken's theory of the structure of this form of carbon.

Aggregation of Small Particles.—A very remarkable instance of the aggregation of small particles has been described by H. S. Patterson, R. Whytlaw-Gray, and W. Cawood in their paper on the structure and electrification of smoke particles which appears in the July issue of the *Proceedings of the Royal Society*. An azo-dye, *m*-xylene-azo-β-naphthol, was volatilised on to a slide. At first a mixture of red supercooled spherical droplets and closely packed crystalline aggregates was formed. Then, on standing, some of the crystalline particles proceeded to develop hair-like tails which were both long and extremely tenuous. As the tail grew, the crystal aggregate diminished in size, and in addition surrounding droplets evaporated, until in the final stages of the rearrangement there were in many cases only the hairs left. The latter were sometimes as long as 0·15 mm., and when a crystalline head still remained, the tail dwindled away from a thickness of the order of 10^{-4} cm. near the head to probably less than 10^{-5} cm. at the other end. No substance other than this particular azo-dye has yet been found to show the effect on any comparable scale. Two good microphotographs of the hairs are reproduced in the paper, and in both the hairs would, in absence of further description, probably be taken to be dirt on the slides.

Dust in New York City Air.—An article by Dr. E. E. Free in the *New York Times* of June 30 describes tests made of the air in New York, in April and May last, to determine the degree of smoke pollution, and the number, size, and character of dust and soot particles in the air at different heights above the street level. The instrument used was the Owens' dust counter. Ultra-violet radiation was examined by a spectroscope. The greatest number of particles counted in any sample was 910,000, the lowest 250,000 per cub. ft. It is stated that rain greatly decreases the dust in the air and that the chief source of dust appears to be domestic fires. The heaviest rain never reduces the dust content of the air to zero, and a heavy downpour was less efficient as a dust remover than a thin, long-continued drizzle. The quantity of dust at any place

is governed chiefly by wind direction. An important fact brought out was the decrease of dustiness above street level, so that at about 200 ft. up the dust was reduced by 25-50 per cent. The New York dust was found to consist chiefly of grains of soot, averaging 1/20,000 of an inch diameter. It is assumed that these are removed from the air by settlement after aggregation into larger masses. This is not supported by evidence, and the removal of the particles from the city by the wind does not appear to have been taken fully into account. A discrepancy is indicated between the results of these tests and others made by the Carrier Engineering Corporation. The latter indicated some 2000 tons of solid matter in the air above the city, while the tests described indicated about 4 or 5 tons. It is stated that, from the middle of October to about the middle of April, no measurable trace of ultra-violet radiation reaches even the tops of the buildings in mid-town New York.

A New Valve Effect.—An important new effect in thermionic tubes is described by K. H. Kingdon and E. E. Charlton in the June number of the *Physical Review* (p. 998). It had been found that hot filament tubes containing a trace of cæsium vapour could act as very sensitive detectors of radio signals under certain conditions, and a more detailed investigation showed that this was not being brought about through curvature of the characteristic curves. It was ultimately found that what was apparently occurring was that the cæsium was being ionised at the surface of the filament and then accumulating in the positively charged state near the region of minimum potential which surrounds this electrode, where it modified the space-charges in such a way as to increase the electron current to the grid and anode. The ions have a natural period of vibration about the surface of minimum potential, and when acted upon by an alternating electromotive force of the same frequency, are set into resonant vibration; being then more diffusely spaced, they exert less control on the electron current, which is thus reduced. The calculated and observed periods of the ions are of the same order of magnitude. In a further note by K. H. Kingdon (p. 1075) it is mentioned that a similar effect can be produced by ions generated by electronic impact between the grid and anode, and that their response is sufficiently selective to permit of the resolution of separate rectification peaks for each of the isotopes of neon and argon.

Determination of the Chemical Constituents of Petroleum.—The Bureau of Standards of the U.S.A. is co-operating with the American Petroleum Institute in an investigation for the separation and identification of the constituents of petroleum, and the apparatus and methods in use are described by E. W. Washburn, J. H. Bruun, and M. M. Hicks in the March issue of the Bureau of Standards publication, *Journal of Research*. Details are given of a number of stills of various types, and an interesting part of the paper deals with molecular stills, first used by Brönsted and Hevesy for separating the isotopes of mercury. An apparatus for the combustion analysis of hydrocarbons up to C_{100} is also described, the accuracy of determination of both carbon and hydrogen being about $\pm 0{\cdot}05$ per cent. It has been found possible to carry out the distillation of petroleum at high temperatures without cracking, provided that all air is excluded. A note is included in the paper directing attention to the fact that the danger of poisoning from mercury spilled in laboratories is probably very small owing to the rapid contamination of the mercury surface with oil or grease.

Locomotive Performance.—Mr. E. C. Poultney, in the *Engineer* for July 5 and 12, discusses the comparative efficiencies of two American locomotives—one of the Pacific 4-6-2 type and another of the Atlantic 4-4-2 type—working under varying conditions of speed. In the same journal in 1924 Mr. Poultney dealt with the boiler efficiency and cylinder efficiency of these engines, but in the present articles he treats of the complete locomotive, taking into consideration the combined efficiency of the unit as a whole. He first considers the mechanical efficiency or the power absorbed by the engine in moving its working parts; he shows how fuel consumption is related to power, and gives the fuel and steam rates per dynamometer horse-power and their relation to speed in miles per hour. Other sections of his articles are devoted to superheat and thermal efficiency, boiler efficiency, cylinder efficiency, and, finally, locomotive performance. Each section is illustrated by curves for the two engines, and in a table he gives some interesting figures of the Pacific engine working at varying speeds with a constant cut-off and at constant speed with varying cut-off. In the first instance, the engine was run at speeds rising from 120 r.p.m. to 320 r.p.m., the I.H.P. ranging from 972 to 2290; the efficiency at the same time fluctuating between 5·96 per cent and 7·61 per cent; in the second instance the engine speed was kept at 240 r.p.m., but the cylinder cut-off altered from 20 per cent to 50 per cent. Here the lowest locomotive efficiency was 4·56 per cent and the highest 6 per cent. Comparing the two locomotives when being used under the best conditions for economy in the use of the heat units available in the fuel fired, the Pacific engine showed a decided superiority over the Atlantic engine.

Rating Electric Lamps.—During the last twenty years considerable progress has been made in the standardisation of electric lamps. Formerly it was the custom to buy lamps rated as 8, 16, 32 . . . candle-power. We now buy lamps according to the electric power they require; for example, 10, 20, 30 . . . watt lamps. It may be argued that what a consumer wants to buy is a device to give light and not a device which takes a specified amount of power. This is recognised by the manufacturer. It is much easier to measure electric power than it is to measure candle-power, and the ratio of the two in different types of lamps is known approximately and is often given. It is certainly much easier to rate lamps by the power they take and it can be done more accurately. We think, however, that the approximate candle-power should also be marked on all lamps. Naturally, if the rated watts proceed by decimals, the rated candle-powers do not proceed by decimals, and the differences between them vary according to no simple law. In an official specification published in March last by the U.S. Bureau of Standards, the amounts of the tolerances permitted both from the rated electric power and from the rated light-giving efficiency are given for electric lamps with tungsten filaments. With a 40 watt lamp, for example, the candle-power per watt may vary from 7 per cent below to 7 per cent above the standard efficiency. The corresponding admissible power variation from the standard is 5 per cent. In another official American specification for miniature lamps, issued at the same time by the Bureau of Standards, we find that the average life of miniature tungsten filament lamps for flash-light service varies from 5 to 14 hours, and for automobile service it varies from 100 to 360 hours. The life of a lamp is supposed to be finished when the light it gives has fallen by a definite percentage from its initial value.

Protection from Lightning.

THE desirability of protection from lightning was recognised from the earliest times. The earliest attempts consisted of exorcisms by priests, the wearing of charms, the ringing of church bells, and even the burning of witches. It was not until about 1750, when Franklin proved that a lightning flash was an electrical phenomenon and could be guarded against by suitable conductors, that these superstitions began to die away. Still, it is only of recent years that, mainly owing to the work of Lodge, the true function of these conductors has begun to be understood by physicists. Engineers are now putting into practice what they learn from theory and discover from high voltage experiments. Finality, however, is still far from being attained. We welcome, therefore, the new Code [1] for protection against lightning, which has recently been issued by the U.S. Bureau of Standards and the American Institute of Electrical Engineers.

In this book instructions are first given to guide the conduct of persons during thunderstorms. Then the methods of protecting buildings and miscellaneous property are described, and finally how structures containing inflammable liquids and gases can be safeguarded. In the appendix an account is given of various kinds of 'lightning' discharge and a brief notice of various recent theories.

So far as the rules given for personal conduct during a thunderstorm are concerned, we think they are reasonable. There is no shutting of windows, pulling of blinds, and lighting of candles, customs still adhered to in some places. Neither are nervous people told to go and lie in an empty metal bath, although the advice may be psychologically sound. Lightning fatalities are very rare, and only about ten per cent of them happen to persons who are indoors. All one has to do, therefore, is to stay indoors and keep away from fireplaces, stoves, and other metal objects.

If one is out-of-doors, the following shelters in order of preference are given: (1) Large metal or metal-framed buildings, (2) dwellings having lightning conductors, (3) large buildings or (4) small buildings. If one has to remain out-of-doors, keep away from (1) small sheds and shelters in an exposed position, (2) isolated trees, (3) wire fences, or (4) hilltops and wide open spaces. If one is in the 'wilds', seek shelter in (1) dense woods, (2) a grove of trees, (3) a cave, (4) a depression in the ground, (5) a deep valley or gorge, or (6) the foot of a steep or overhanging cliff. These rules are, of course, not perfect, but their brevity and generality should make them acceptable.

In specifying lightning conductors, we were interested to see that it is apparently immaterial what metal or alloy is used in their construction or what is the shape of their cross section. Instructions are given in the methods used for preventing them from deteriorating. If they are subjected to the direct action of chimney or other corrosive gases, the useful advice is given that they should be protected by a continuous covering of lead not less than one-sixteenth of an inch thick. We are told that the use of glass balls as ornaments on lightning rods is not objectionable. We suppose that this means that the lightning rod is just as efficient when a glass globe is placed on the top of it. We remember being told that during the South African war, British soldiers used to put empty bottles on the top of their tent-poles in the hope that this would prevent their tents being struck by lightning. The methods described of earthing the conductors are quite satisfactory, and no undue stress is laid on the ohmic resistance of the 'earth'.

During the War, several cases occurred of captive balloons and airships being struck by lightning. Fires also were caused by the long sparks which sometimes take place between the airship and the earth at the landing place. These experiences are reflected in the rules. Captive balloons are now earthed through the metal cable and winch by a pipe or tube driven six feet into the ground. Free balloons and airships are provided with an effective earthing wire which is lowered just before landing. It makes contact with a good earth and thus the electrical charges which may have accumulated on them when in the air are conveyed harmlessly to the earth.

In the United States, the protection of valuable or historic trees from lightning by means of conductors is being done on a rapidly increasing scale. In general, a single conductor is run from the highest part of the tree to the earth connexion. If, however, the tree has large branches, conductors are extended to their extremities. Somewhat elaborate arrangements depending on the size of the tree are used for earthing. A shallow network is used to collect the current near the surface of the earth so as to protect the roots of the tree, which experience has shown are as likely to be damaged as the tree itself. It is an excellent plan also to put lightning conductors on trees the neighbourhood of which is frequented by livestock. Full instructions are given for mitigating the dangers arising from wire fencing. Fences are earthed by means of iron posts or, more cheaply, by driving lengths of galvanised iron pipe at least three feet into the ground and attaching it by ties of galvanised wire to the fence. In addition to earthing the fence, its electrical continuity should be broken by breaking the wire at intervals of about a thousand feet and joining up the breaks by insulating material.

Full details are given of excellent methods for protecting structures containing inflammable liquids and gases from lightning. All-steel gas-tight tanks with vents adequately 'flame-proofed' are considered to be completely protected. So also are tanks with floating roofs, which prevent the accumulation of explosive mixtures, provided that there is provision for minimum exposure of the contents.

In an interesting appendix the origin, characteristics, and effects of lightning are described. An ordinary flash of lightning is called streak lightning. In rocket lightning, the growth is so slow that it reminds one of a rocket. In bead lightning we have a string of luminous globes separated by darker intervals. There are other forms such as sheet and globular lightning and St. Elmo's fire.

A brief résumé is given of Simpson's and C. T. R. Wilson's results, and an excellent photograph, taken by a moving camera, is shown, which proves that a flash can be rapidly intermittent. Instructive data taken from U.S. Weather Bureau publications show the frequency of thunderstorms in various places in the United States. A sequel to this code will deal with electrical apparatus and power lines, and it will be of great interest, as there are considerable divergencies in American and Continental practice.

A. R.

Studies in Oxidation-Reduction.[1]

THIS bulletin, obtainable for a mere half a dollar, consists of reprints of the masterly series of researches published by W. Mansfield Clark and his associates from 1923 onwards. Twelve pages of supplementary notes have been included. The principal author, well known for his valuable book on "The Determination of Hydrogen Ions", was quick to appreciate that Gillespie's measurements of the electrode potentials induced by bacterial reduction, published in 1920, revealed a method whereby it might be possible to accumulate *quantitative* data concerning oxidation and reduction. The first paper outlines the theoretical aspect of the problem and shows how it is possible to express relative oxidation-reduction intensities in terms of electrode potential. For each system a constant can be found which is a measure of its oxidation-reduction *intensity*, a matter quite apart from the *capacity* of a solution to oxidise or reduce. A series of substances can therefore be arranged, so that when themselves in the half-oxidised or half-reduced state, each one will tend to oxidise one with a more negative constant, and to reduce one with a more positive constant.

The second paper is devoted to a consideration of the theoretical relations between reduction potentials and hydrogen ion concentration. Oxidation or reduction will displace *p*H in one direction or another in accordance with the acidic or basic nature of the group destroyed or created.

The third of the series relates to an experimental study of the electrode potentials of 1-naphthol-2-sulphonic acid indophenol and its reduction product. It includes a valuable description of apparatus and methods.

The fourth deals similarly with the indigo sulphonates, and the fifth with simple indophenols, dibromo substitution products of phenol indophenol and substituted indophenols of the ortho type being studied in the sixth, while the seventh discusses the dichloro substitution products of phenol indophenol.

The eighth is devoted to methylene blue, a substance of great histological and physiological interest, since it is a most useful *intra vitam* stain. The bibliography on methylene blue occupies nineteen pages, with about four hundred and fifty citations, and is probably the most complete in existence.

The ninth is entitled "A Potentiometric and Spectrophotometric Study of Meriquinones of the *p*-Phenylene Diamine and the Benzidine Series". The behaviour of these substances is so complicated, and the tendency to autoxidation is so considerable, that the authors consider it extremely dangerous to draw conclusions from colour reactions with benzidine, *p*-phenylene diamine, and their homologues. In view of the vogue these substances have had as oxidase reagents, the warning should not be forgotten.

The tenth deals with reduction potentials in cell suspensions. Relatively wide spans of potential are covered. Various aspects of the experimental data seem to indicate that cell suspensions are poorly poised with respect to the electromotively active material present at any moment, but that active material is slowly mobilised by cell catalysts from some large reserve. Several of the implications of current theories regarding biological oxidation and reduction are discussed. This discussion and the experimental data lead to the conclusion that the immediate problem is a clearer definition in *experimental* terms of the isolated chemical systems found in the cell.

The supplementary notes supply valuable additions and some trenchant criticism of subsequent work. Attention is directed to the necessity for a clear distinction between "the intensity factor measured in any proper terms but expressed by us in volts, and the capacity factor expressed in chemical equivalents or in faradays". The product is a work term and has nothing whatever to do with kinetics. "Therefore the term reducing *power* (power involves a *time* factor) should never be applied in descriptive text dealing with equilibrium states. The term *reducing ability* is often meant where *reducing power* is used."

The eleventh paper of the series, dealing with toluylene blue, is not included, but some data concerning this compound are included in the supplementary tables.

It cannot be pretended that these papers are anything but difficult reading; the conceptions set forth in them are, however, of fundamental importance; one can search current text-books in vain for any mention of them—though the series started in 1923, and the tenth appeared in 1926. It is to be hoped that all future workers on plant and animal respiration will carry on their researches with a due regard for the theoretical considerations and the exact quantitative data presented by this brilliant American chemist and his collaborators. In its orderly correlation of a large mass of data, in a region which before was in chaos, one is reminded of Loeb's work on "Proteins and the Theory of Colloidal Behaviour".

University and Educational Intelligence.

EDINBURGH.—Dr. Thomas W. M. Cameron, of the London School of Hygiene and Tropical Medicine, has been appointed lecturer in helminthology in the Department of Zoology of the University and in the Royal (Dick) Veterinary College. Mr. A. L. Bennett has been appointed lecturer in zoology in the University.

MANCHESTER.—The Council has appointed Mr. N. F. Mott to be lecturer in mathematical physics.

The Grisedale Scholarships for biological research have been increased in value to £200 each, and awards have been made to Dr. Miriam K. Bishop (botany) and to Mr. Ieuan Thomas (zoology).

SIR FRANK HEATH has accepted the invitation of the executive committee to become the secretary of the Universities Bureau of the British Empire. Sir Frank Heath was permanent secretary of the department of Scientific and Industrial Research, and previously principal assistant of the Board of Education for England and Wales in charge of the universities and training colleges branch of the Board.

THE London County Council has awarded Robert Blair fellowships, which carry a grant of £450, to Mr. C. G. Davies, of Gorseinon, Glamorgan, and to Mr. G. L. Riddell, of Muswell Hill, London. Mr. Davies, who is works manager of the Grovesend Steel and Tinplate Company, Gorseinon, will carry out a detailed investigation into modern developments of practice in steel sheet, tinplate, and galvanised sheet manufacture in the United States. Mr. Riddell will study printing and its allied trades in relation to its machinery processes and methods of production in Canada, the United States, and Germany.

FOLLOWING on the representations made in Australia last year on behalf of the Colonial Office by Major R. L. Furse, the Prime Minister has appointed a central committee of advice in connexion with the

making of selections from graduates nominated by the various Australian universities for appointment to the Colonial Service. The chairman is General Sir Brudenell White, and the other members are the Hon. F. W. Eggleston, Dr. J. H. L. Cumpston, Dr. A. C. D. Rivett, Major Keith Officer, and Mr. S. S. Addison (secretary). This move will be appreciated in the Commonwealth, though it is improbable that many candidates will be available for some years for scientific posts in the Colonies, particularly in biological divisions of work.

THE following awards for the year 1929–1930 have been made by the Salters' Institute of Industrial Chemistry and approved by the Court of the Salters' Company. Fellowships have been renewed to: Mr. C. G. Akhurst, Imperial College, London (Fellow, 1927–1929), for a further year at the Imperial College of Tropical Agriculture, Trinidad; Mr. H. K. Cameron, University College, London (Fellow, 1928–1929, at the University of Munich), for one year; Mr. H. Diamond, University College, London (Fellow, 1928–1929, at the University of Munich), for one year; Mr. F. L. Gilbert, University College, Nottingham, and Cambridge (Fellow, 1928–1929, at Cambridge), for one year; Mr. C. H. Lea, University of Liverpool (Fellow, 1928–1929, at Cambridge), for a further year at the Low Temperature Station, Cambridge. Fellowships have been awarded to Mr. C. G. Eltenton, Trinity College, Cambridge; Mr. D. L. Hodge, Imperial College, London; Mr. L. C. Bannister, Universities of Liverpool and Cambridge. The Institute has also awarded one hundred grants-in-aid to young men and women employed in chemical works, to facilitate their further studies.

IN several articles in the *Times of India*, under the title "Mathematics and Life", published last year in pamphlet form, Prof. John Maclean, Wilson College, Bombay, advocates a reform in the teaching of mathematics in the first year of university study. Hitherto at Bombay the student who is not a mathematical specialist has looked on mathematics as a fence that he must climb as best he can and then forget about, as a mere obstacle without connexion with his future life. Prof. Maclean's aim is to give the student an equipment of mathematics that will be of direct use to him in after life, whatever walk in life he may have chosen. His course would exclude all portions of mathematics that have no direct application and would give a thorough training in the more useful parts of the subject, using as illustrations problems from various walks in life; it may be problems such as arise in the career the student has chosen, it may be problems with a close resemblance to those of his career and appropriate to be dealt with by the same mathematical tools. Prof. Maclean believes that in this way he will replace the deadening teaching of the past by teaching that will make the mind alert, and the mathematical knowledge available on every occasion—he will substitute an effective education for a nugatory one. Although the universities of Great Britain show no comparable development, our schools have, during the present century, gone through the change advocated, by the scrapping of the branches of mathematics that lead nowhere and by aiming at contact with reality in the retained branches. The effect of this change on the pupils has been remarkable. The old style teaching was understood by about five per cent of the pupils, and the idea prevailed that mathematics was a special gift. On the new lines, every pupil understands and readily applies his knowledge to his own problems. We wish all success to Prof. Maclean, who is a pioneer for the university of the reform that has proved of such value in the school.

Calendar of Patent Records.

August 3, 1822.—Machine saws for felling tree have not found great favour, but many have bee invented. An early example was the subject o Mouret's patent granted for five years in France o Aug. 3, 1822. The saw is mounted on rollers and i moved to and fro by manually operated gear, bein guided in a frame so as to have a slightly circula motion. The frame itself is also on rollers, and i caused to advance slowly towards the tree with eac cut of the saw by means of weights and rop gearing.

August 3, 1832.—A 'bachelor' button which coul be attached to the garment without sewing—a typ that became very popular during the War—wa patented by John Christopher of London on Aug. 3 1832.

August 4, 1877.—The gas engine was established o a firm basis, and for the first time became a seriou competitor of the steam engine as a prime mover, whe Nikolaus Otto introduced the four-stroke engine whic he patented in Germany on Aug. 4, 1877. Otto ha been working at the problem for more than twent years, and had already in 1867 achieved partial succes with the Otto and Langen engine, but the new engin entirely superseded all others and monopolised th world's markets for many years. The improvemen was very largely due to the re-introduction of Barnett' proposal to compress the charge of gas and air befor ignition (cf. Calendar of Patent Records, April 18).

August 5, 1551.—An early reference to tin-plat manufacture and what appears to be the first instanc of a German patent grant is given by Beck in hi "Die Geschichte des Eisens", when he records tha on Aug. 5, 1551, King Ferdinand granted to Freihe Hanns von Ungnad of Steiermark the privilege to erec one or more mills for the manufacture and tinning o sheet-iron and to carry on the trade unhindered fo a period of twenty years, "in Bedacht der ansehn lichen, nützlichen, beharrlichen, hocherspriesslichen Dienste, so er sider Eingang unsrer landesfürstliche und königlichen Regierung mit ungespartem, seine Leib und Gut willig und unverdrossenlich bewiese hat".

August 8, 1777.—The first patent for a milk chur was that granted on Aug. 8, 1777, to John Rastric of Morpeth, the engineer. The churn is in the for of a barrel, with a central shaft having several set of 'dashers' and rotated by means of an externa handle. A ventilator is fixed upon the barrel.

August 9, 1913.—The possibility of the hydrogena tion of coal to oils has been recognised for many year and a great deal of experimental work has been carrie out to arrive at a practicable process, but the proble was not solved until Bergius introduced his method o subjecting bituminous coal to the action of hydroge at pressures of from 200 to 300 atmospheres an at temperatures of from 300° to 500° C., which h patented in Germany on Aug. 9, 1913. Though th technical difficulties, however, have been overcom the cost of production remains at present too high t admit of the process being commercially successful i competition with mineral oil production.

August 10, 1874.—One of the pioneers of the moder aerial ropeway system of transportation was th German engineer Adolf Bleichert, who was mainl responsible for the development of the two-ro system in which there is a fixed carrying rope and separate hauling rope, in contrast to that introduce in Great Britain in which a single endless movin rope to which the carriers are fixed is employe Bleichert's first patent was granted in Saxony o Aug. 10, 1874.

Societies and Academies.

PARIS.

Academy of Sciences, June 24.—**Marcel Brillouin**: Movements of the oceans. The Newtonian potential of the ridge in cylindrical co-ordinates.—**B. Cabrera** and **A. Duperier**: The paramagnetic properties of the rare earths. Details of measurements of the variations of the magnetisation coefficients of sulphates and oxides of the rare earths between 20° C. and 400° C. The Curie-Weiss law applies to some of the rare metals, but not to all.—**F. E. Myard**: The correct control of a motor-car.—**Bertrand Gambier**: Geometrical configuration of right lines or circles.—**S. Finikoff**: The periodic series of Laplace containing W congruence.—**Pasquale Calapso**: Rectilineal congruences on focal surfaces to which correspond lines of curvature.—**Georges de Rham**: Multiple integrals and *Analysis situs*.—**Maurice Gévrey**: Hypotheses concerning the solution of problems at the limits of the elliptic type.—**J. Delsarte**: A fundamental problem of the theory of vortices.—**R. Wavre**: A desideratum formulated by Tisserand and the theory of planetary figues.—**Marcel Chopin**: High temperature determinations of the specific heat of nitrogen and carbon dioxide. The method used aims at the nearly complete elimination of the corrections in a calorimetric measurement of the specific heats of gases at high temperatures. For nitrogen,

$$C_p = 6{\cdot}82 + 0{\cdot}00058t,$$

and for carbon dioxide,

$$C = 8{\cdot}9 + 0{\cdot}61(t/100)^{0{\cdot}673}.$$

These results are compared with earlier data.—**C. Caveau**: There is no second law (of thermodynamics). Outline of a concrete thermodynamics.—**R. Darbord**: Electrostatic calculations concerning the electric discharge between two spheres.—**Fahir Emir**: Superficial layers and superficial solutions of myristic acid. The thickness of the saturated film of myristic acid is 16 A. This is exactly half the distance found by the X-ray method (Becker and Jancke) for the solid acid, and confirms the hypothesis of Marcelin.—**Pierre Chevenard** and **Albert Portevin**: The phenomena during reheating of hypertempered steels.—**A. Hanfourche**: The oxidisability of silicon and the allotropic modification of Moissan and Siemens. Experiments on the effect of the state of division of silicon on its oxidisability and solubility in hydrofluoric acid.—**M. Tian**: The solidification of saccharose. Catalysis by water.—**A. Travers** and **Schnoutka**: The hydrated polycalcium aluminates.—**Ligor Bey** and **M. Faillebin**: The reaction of resorcinol and a new coloured indicator.—**E. Bœdtker** and **R. Kerlor**: The synthesis of a dicymyl,

$$p\,.\,p - CH_3\,.\,C_6H_4 - C(CH_3)_2 - C(CH_3)_2 - C_6H_4(CH_3).$$

—**A. Wahl** and **J. Lobeck**: The naphthisoindigotines.—**Paul Fleury** and **Jean Marque**: The reducing power of the polyalcohols towards alkaline solutions of potassium iodomercurate. The amount of reduced mercury can be utilised under certain well-defined conditions for the quantitative determination of mannitol, inositol, dulcitol, and glycol.—**L. Petitjean**: The acceleration of masses of air in atmospheric movements.—**Jean Lugeon**: A method of determining from a great distance the geographical position and velocity of certain discontinuities or meteorological disturbances by means of the atmospherics they emit.—**G. Nicolas** and **Mlle. Aggéry**: *Cerasus Caroliniana*, new example of andromonœcia. A new type of bacterial disease.—**Mlle. M. L. Verrier**: The structure of the eyes and the physiology of vision in selachians. The eyes of selachians (*Scyllium*, *Mustelus*, *Acanthias*, *Raja*) are inferior to those of the majority of other fishes.—**Gruvel**: The influence of the piercing of the Suez Canal on the marine fauna of the coasts of Syria. A description of about a dozen species of fish which have passed into the Mediterranean from the Indian Ocean and the Red Sea.—**P. Vignon** and **E. Séguy**: The presence of the raised median nervure in the Diptera.—**G. Mouriquand** and **A. Leulier**: The antirachitic action of certain cholesteric lipoids in *Helix Pomatia*.

GENEVA.

Society of Physics and Natural History, June 6.—**E. Rogovine**, **L. Wohlers**, and **P. Wenger**: A micro method for the determination of uric acid. The method, described in detail for practical applications, is based on oxidation by excess of potassium ferricyanide followed by a back titration of the excess of ferricyanide.—**Th. Stephani** and **E. Cherbuliez**: Researches on antituberculous chemotherapy (copper and the rare earths). The use of the copper and didymium derivatives of di-iodosalicylic aldehyde and of copper benzoate in solution in oil (they are insoluble in water) has given very encouraging results in the treatment of tuberculosis of the guinea-pig and also in man. These substances are innocuous and their cost is small.—**E. Briner** and **R. Wunenburger**: The ozonation of acetylene. The ozonation of this hydrocarbon with a triple bond has given rise to glyoxal, that is to say, to a substance containing the same number of carbon atoms as the hydrocarbon submitted to ozonation. On account of its great instability, the ozonide of acetylene has not been prepared in the pure state.—**Basile Luyet**: Sensitivity to the ultra-violet in *Mucor* as a function of age. Experiments have been made on *Mucor hiemalis*. By irradiating cultures of ages from 1 to 38 hours, it has been found that up to the age of 22 hours the fatal dose is 10 to 20 sec. and that it changes suddenly to 20 min. when the sporangia have been formed.—**F. Chodat**: The genetics of strawberries. Heterosis. Crossing the Dufour and Moutot varieties has given a very vigorous hybrid. The proportion of large plants was 62 per cent for the hybrid against 4·5 per cent in the Moutot descendants and 15 per cent in the Dufour descendants.

WASHINGTON, D.C.

National Academy of Sciences (*Proc.*, Vol. 15, No. 3, Mar. 15).—**Otto Struve**: The longitude of the galactic centre as derived from the intensities of detached calcium lines (see NATURE, May 11, p. 737).—**Milton L. Humason**: The large radial velocity of N.G.C. 7619 (see NATURE, May 25, p. 811).—**Edwin Hubble**: A relation between distance and radial velocity among extragalactic nebulæ (see NATURE, May 25, p. 811).—**Harlow Shapley**: Studies of the galactic centre. (4) On the transparency of the galactic star clouds (see NATURE, May 11, p. 737).—**Selig Hecht** and **Ernst Wolf**: The visual acuity of the bee and its relation to illumination. Visual acuity was measured by the determination of the minimum illumination required to produce response to movement of patterns consisting of equal black and white bars. It varies with illumination much as does the human eye, being poor at low illuminations, and increasing with increased illumination, at first rapidly and then slowly, to a maximum. The maximum for both is between 50 and 100 millilamberts, but the human eye can resolve the environment about a hundred times better than the bee's eye. Bees can resolve the environment much more accurately vertically than horizontally. The results are in accord with anatomical findings.—

C. F. Roos: Some problems of business forecasting. Given the necessary supply functions, cost of production functions, etc., available to most business undertakings, it is possible to compute useful figures referring to replacement and enlargement of plant.—**Victor K. La Mer** and **J. W. Temple**: The autoxidation of hydroquinone catalysed by manganous salts in acid solutions: a reaction whose velocity is proportional to the driving force.—**George B. Kistiakowsky**: The temperature coefficients of some photochemical reactions. The rates of reaction of stoichiometric mixtures of hydrogen and oxygen and of carbon monoxide and oxygen have been investigated; the temperature coefficients increase with rising temperature.—**M. H. Stone**: Linear transformations in Hilbert space. (1) Geometrical aspects. Transformations in complex space which may be applicable to the formulation of the quantum theory.—**Neal H. McCoy**: On commutation rules in the algebra of quantum mechanics.—**H. S. Vandiver**: Some theorems concerning properly irregular cyclotomic fields.—**Gilbert N. Lewis** and **Joseph E. Mayer**: The thermodynamics of gases which show degeneracy (*Entartung*). A mathematical extension, to all types of molecules, of the work of Bose on photons and of Einstein on monatomic molecules.—**Albert W. Hull** and **Irving Langmuir**: Control of an arc discharge by means of a grid (see NATURE, May 18, p. 776).—**Joseph Kaplan**: The heat of dissociation of nitrogen. The value found from a consideration of the energy of the nitrogen molecule in the *D*-level is about 9 volts.—**Katharine B. Blodgett**: Exponential yield of positive ions in argon.—**F. Rasetti**: On the Raman effect in diatomic gases. Observations on nitrogen, oxygen, and carbon monoxide give results in good agreement with theory.—**Carl Barus**: Adiabatic expansion in case of vanishing increment (2).—**Edwin H. Hall**: On electrons that are 'pulled out' from metals. The 'free' and 'associated' electrons of the author's dual theory of metallic conduction are renamed 'thermions' and 'valence electrons'. A discussion of Millikan and Eyring's experimental results on the basis of this theory. The evidence indicates that the thermions are very few compared with the number of atoms (1 to 10^5 or 10^6). Valence electron conduction is effected by intermittent trains of electrons.—**Carl E. Howe**: A preliminary report on the measurement of the *Kα* line of carbon. Measurements were made by reflection at grazing incidence from a ruled grating in a vacuum spectrograph. The unweighted mean was $44{\cdot}60 \pm 0{\cdot}04$ A.—**F. Zwicky**: On the imperfections of crystals. The differences between the theoretical and observed breaking strength of crystals has led to a theoretical examination of suggested microscopical cracks in crystals. The phenomenon may be related to cold-hardening and similar effects.—**Leonard J. Neuman**: The mechanism of spark discharge. In argon at low pressures with nickel grid and sodium-coated electrodes, the liberation of electrons from the cathode by bombardment with swift positive ions is the predominating mechanism; with increasing pressure, generation of electrons in the gas by collisions between swift positive ions and neutral molecules becomes more important.—**John W. Gowen**: The cell division at which crossing-over takes place. It occurs in *Drosophila* in the chromosomes as they prepare for the first maturation division.—**George H. Shull**: An unexpected association of factors belonging to three linkage groups in *Œnothera* and its explanation.—**George D. Snell**: An inherent defect in the theory that growth rate is controlled by an autocatalytic process. The increasing volume of the growing organism invalidates the usual mass action equation applied to growth processes. Appropriate equations are derived.—**Robert Emerson**: Chlo phyll content and rate of photosynthesis. T chlorophyll content of *Chlorella vulgaris* can be c trolled by culture in a medium containing appropri salts, glucose, and less iron than is normally used. high light intensities, photosynthesis is a function chlorophyll content. The curves for rate of pho synthesis as a function of temperature at differe chlorophyll contents are similar in form.—**Morg Upton**: Functional disturbances of hearing in guin pigs after long exposure to an intense tone. There first an increase of sensitivity to the exposure f quency and then desensitisation to all intensities o but no general change in the auditory mechanis This is evidence for a 'resonance' theory of heari —**Thomas Wayland Vaughan**: Studies of orbitoi Foraminifera: the subgenus *Polylepidina* of *Lepi cyclina* and *Orbitocyclina*, a new genus.

Darwinism and Social Ethics.

THE Bishop of Exeter, in the July number of the *Hibbert Journal*, lays his finger upon two implications of Darwinism which appeal to many as subversive of social tendencies as they exist to-day, and as they have been encouraged especially by Christianity. The first is the theory of the struggle for existence, which he regards as nothing more than a policy of destruction, forgetting that, as Kropotkin emphasised long ago, destruction is not the whole story, but that mutual aid and combination also play an effective part in the struggle in the lower as well as in the higher orders of Nature. Especially in the higher orders, it is noteworthy that spiritual and intellectual progress has been associated with the development of mutual aid and sociality, and it seems likely that along these lines future progress is most likely to be attained.

The Bishop's own examples of the help given by civilised peoples in the stamping out of disease amongst the lower races, or in the betterment of the lot of the less fortunate amongst their own people, show how clearly spiritual development (which also is evolutionary) has changed the crude notion of destructiveness. The struggle for existence is often a delicate and not very obvious process. Amongst men it has certainly lost much of the crudeness and literalness which it possesses in the world of the lower animals, and the evolution of spiritual development ensures that amongst men there can be no return to the purely physical struggle which is sometimes taken as the whole story in the lower orders.

On the other hand, it is obvious that selection of some sort must take place amongst men, and there is a real danger in the unlimited preservation of the unfittest in mind or body, always, be it noted, at the expense of the more fit. It is difficult to avoid the conclusion that, since man as he has evolved has to a large extent done away with the selection which would have resulted from an exposure to the pressures of Nature, and has replaced that by an effort after general well-being, he must accept the responsibility entailed, and, as Prof. J. Arthur Thomson once expressed it, must "continue in a subtler, more rational, more humane form the automatic singling and sifting which goes on in Nature".

The Bishop of Exeter's second difficulty lies in the specialisation apparent in the structures and functions of animals, which, applied to mankind, suggests to him the need for a political system

fundamentally different from the one under which we are at present living; one which will promote classes with specialised functions. "The equality of men is a Christian ideal, but one which should prove subversive to all evolutionary development." But the Bishop's earlier examples of higher races and lower races, of fit and unfit, show that he is no firm believer in equality, and it is evident enough that men are not equal in bodily or mental development, in spiritual development, or capacity for spiritual development.

It must be remembered that specialisation in structure or function is a device to meet a special set of circumstances, and that it implies a lessened ability to meet fresh changes in circumstances, as many extinct groups of animals bear witness. Man is still evolving, and he would be rash who would predict the developments which may be required to meet the changing circumstances of his environment.

The safety of humanity lies not in specialised and therefore fixed castes, but in the mental capacity which enables man to adapt his whole life to the needs of different conditions, as no lower animal can adapt itself. Perhaps the only safe generalisation is that neither bodily evolution alone nor mental evolution alone is likely to be of great survival value, but that sound minds in healthy bodies must combine in a co-operative social evolution wherein the individual will gradually come to mean less and progressive humanity will mean more.

A Source Book of Astronomy.

A Source Book in Astronomy. By Prof. Harlow Shapley and Helen E. Howarth. (Source Books in the History of the Sciences.) Pp. xvi+412. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1929.) 20*s.* net.

THIS book is a sheer delight. The multiplication of text-books and popular literature in astronomy, salutary as it is on the whole, has one serious disadvantage: it diverts the attention of inquirers from original sources of knowledge. The reason is obvious. Neither time nor accessibility allows of reference to a separate volume for each piece of information one may require. We need all our store of available knowledge between two covers, and so it comes about that the amateur, nourished on his handbook, and the student, looking only to his text-book, develop into the working astronomer with an almost total ignorance of the original papers of any but contemporary writers. One could probably say with truth that mo astronomers who read this volume will read th greater part of its contents for the first time, an yet it contains nothing that can be ignored witho loss or that can be assimilated from any paraphra with quite the same benefit.

In June 1924, Mr. Gregory D. Walcott, of Lon Island University, Brooklyn, N.Y., assembled a advisory board of philosophers and men of scienc with the object of producing a series of "sourc books" in the history of the sciences which woul "present the most significant passages from th works of the most important contributors to th major sciences during the last three or four cen turies". Among the members of the board wa Prof. Harlow Shapley, of Harvard College Observa tory, and he, with the assistance of Miss Helen I Howarth, has now prepared the first of the projecte series, dealing, appropriately, with astronomy. I a brief preface the compilers state some of th difficulties and general characteristics of the worl Several passages which would otherwise have bee quoted are excluded on account of their mathe matical nature or excessive length; Gauss's de scription of the 'method of least squares' is, i fact, the only mathematical note in the book. N contribution originating since the year 1900 ha been included, nor has the work of any livin astronomer been given. Those who wrote i English are represented by their *ipsissima verb* and others by English translations, many of whic have been specially made. A short note giving few relevant facts concerning each of the autho represented (of whom there are more than sixty is appended, and in some instances portraits o other illustrations appropriate to the work de scribed are reproduced. The chronological orde has been followed.

A book of this type, as the authors point out, not a history; it does not aim at completeness, an there is necessarily no attempt to link up one piec of work with another. Nevertheless, it is clear tha the choice has been partly determined by a praise worthy desire to 'see a thing through'. Thu we may follow the history of our knowledge o Saturn's rings through the contributions of Huy gens, Cassini, Maxwell, and Keeler—a consecutiv story. It should be said further that the book in no sense a text-book, on account not merely o inadequacy, but also of radical unfitness. Th authors have wisely refused to restrict themselve to accounts of ideas and discoveries which are sti accepted at their original value. Some of th matter here reprinted has been definitely supe

ded, and some has played a negligible part in ading up to modern views: it is not thereby squalified for a place among the classics of tronomy. The distinctive feature of a 'source-ook' is that it contains the actual words, written ten in the glow of excitement following a great scovery or idea, of those most worthy to be membered, and its peculiar value, we would say, s in the fact that in those words there is an notional, and sometimes a scientific, significance eyond the power of any second-hand account to produce.

It is, of course, impossible in a review to give ren an approximate idea of the character of such book. We can merely cite at random a few of e treasures which it contains. Here, for example, e may read why Copernicus found the geocentric smogony unacceptable, and how Kepler advised m "who is so stupid as not to comprehend the ience of *Astronomy*, or so weak and scrupulous as think it an offence of Piety to adhere to *Copernis*, him I advise, that leaving the study of *stronomy*, and censuring the opinions of Philophers at pleasure, he betake himself to his own ncerns, and that desisting from further pursuit these intricate Studies, he keep at home and anure his own Ground". One may renew acuaintance with Salviatus, Sagredus, and Simicius, and learn from Huygens that the art of nstructing telescope lenses "has in reserve more fficulties than it seems to bear on its face", and om Bradley that the agreement between his servations and the hypothesis of the aberration light "may possibly be thought to be too great those who have been used to astronomical servations". One may read of Horrox and Goodke, the marvellous boys who died immortal at the e of twenty-two, and of how Kapteyn estimated s enthusiasm for the Cape Photographic Durchusterung to be equal to six or seven years of udgery. The feelings of a "watcher of the skies hen a new planet swims into his ken" may be ught in the words of Herschel, but it is doubtful they will be experienced by any but a kindred irit. No such limitation characterises Huggins's count of the spectra of gaseous nebulæ.

In the midst of such an illustrious assembly, it with something of a shock that the reader counters "an extract from the Will of James ck". What is it doing in that galley? If the culiar value of a source book lies in the fact that e words of an original thinker or discoverer may expected to be 'inspired' in the only legitimate nse of the word, on what grounds can be justified the inclusion of a legal document, of all dusty formulæ the most irredeemably dead? This seems to us to be the one serious defect in an otherwise wholly admirable book.

Perfection in such a publication is impossible of achievement, and, since the standard of judgment is inevitably determined in part by individual taste, is probably without meaning. We should have liked to see a quotation from Newton's "Opticks" as indicating the origin of astrophysics, as an example of the ideal manner of describing experimental researches, and as a timely reminder that Newton was not only a great philosopher but also a great experimenter. This seems the more desirable, as the quotations by which Newton is represented, worthy in many respects though they are, contain an undue proportion of misapprehensions. The laws of motion and gravitation, now superseded, could, of course, not be omitted, but was it necessary to repeat the conclusion that "the least particles of all bodies" are "extended, and hard and impenetrable . . . and this is the foundation of all philosophy"? Or that the possibility that the solar system moves among the stars is "an hypothesis hardly to be admitted"? But doubtless every reader will miss some favourite passage or regret the inclusion of some other. It is wiser and more fitting to enjoy the rich treasure so handsomely compiled and presented than to give the rein to individual prejudices.

'Handsome' is not too strong a word for the outward form of this charming book. It is admirably printed and bound, and the reading is a physical as well as a mental pleasure. In matters of detail only two defects have been noticed. On p. 371 the caption under the illustration refers to "ξ Ursæ Majoris" instead of "ζ Ursæ Majoris", and in the account of Horrox's observation of the transit of Venus, it would have been an advantage if the month of observation had been definitely stated in the footnote. H. D.

Crystallochemistry.

Crystal Structure and Chemical Constitution: a General Discussion held by the Faraday Society, March 1929. Pp. iv + 253-422 + 6 plates. (London: Faraday Society; Gurney and Jackson, 1929.) 8*s*. 6*d*. net.

THE Faraday Society is justly proud of its record of general discussions, the subjects of which have covered a wide field during the quarter-century of its existence. The meeting held last March contained an innovation in that

the proceedings started with a formal lecture, and although the subsequent programme was divided into special sections, yet it was Prof. Goldschmidt's opening discourse that sounded the note for all that followed. The report of this conference, which has just appeared, includes all the contributions, many of them by workers distinguished in particular directions in crystallochemistry, and forms a unique collection of opinions and researches upon the nature of the solid state.

Modern theories of crystallography differ from those of even a few years ago chiefly in the method of classifying crystals. Instead of the macroscopic symmetry the atomic environment is now the basic criterion, as expressed by the co-ordination number, *C.N.*; for example, in the well-known rocksalt structure, $C.N. = 6$, meaning that each sodium ion is surrounded symmetrically by six chlorine ions, and vice versa. A combination of X-ray results and optical data has enabled tables of atomic radii to be prepared for the great majority of the elements. This property, however, is not a constant, but depends not only upon the electrical charge but also upon the state of co-ordination. Thus the radius of $S^{6+} = 0{\cdot}34$ A., whereas that for $S^{2-} = 1{\cdot}74$ A. Likewise, the figures for 12-co-ordinated and 4-co-ordinated tin are 1·58 A. and 1·40 A. respectively. These facts show the impossibility of deducing atomic radii correctly, unless crystals are divided into what Goldschmidt calls 'commensurable' groups in which the constituents are in corresponding states of ionisation and environment (or co-ordination).

The quantity *C.N.* is, nevertheless, itself a function of the quotient of the atomic radii of the components, and also of their polarisation or capability of deformation by an electric field. Special types of crystal structure, the molecular lattice and the layer lattice, arise when distortion of the units is very marked. Again, the peculiar nickel arsenide form is found for compounds of the iron family: in these elements the *M*-defect renders the removal of electrons harder than for a metal such as magnesium. Finally, the occurrence of more than one kind of linkage within the crystal is probably responsible for the appearance of the iron pyrites structure, which contains the complex S_2 as a unit.

Prof. Goldschmidt remarks that chemical substitution is the most powerful tool of the investigator in crystallochemistry. Certainly in the hands of the Oslo school it has fashioned a foundation stone upon which to rear a great edifice of systematic inorganic chemistry.

Turning now to the papers contributed to th general discussion proper, those in Part 1 de with inorganic substances, and here again the pa played by atomic arrangement is noticeable. Pro W. L. Bragg's account of the work undertaken Manchester on the silicates provides some fascin ating reading. Broadly, these structures are lik fabrics the stitches of which are groups of oxyge atoms, which groups hold together by commo sharing, while the positive ions are widely disperse throughout the network.

Prof. Lowry and Mr. Vernon present a study the etch figures of sylvine, which confirms i ionic character, and Dr. A. M. Taylor some inte esting reflections upon the AX_4 group, the linkage within which appear to be semi-polar. Othe papers include a contribution by Prof. Jaegar o ultramarine, and one on the fine structure of th felspars by Prof. Schiebold.

The introduction to Part 2 (organic compounds is by Sir William Bragg. Mrs. Lonsdale deals wit the history of the benzene ring question, and wit her own work on hexamethylbenzene. The rin is definitely plane, and the side chain carbo atoms are placed radially to their respectiv nuclear atoms, and lie in the plane of the hexago Dr. Müller describes his hydrocarbon model, an Dr. Piper produces some examples of the ways i which the long spacings (20 A. to 50 A.) of fatt acids have been made to yield valuable data o composition.

Mr. Bernal, in opening Part 3 (metals), produce perhaps the most suggestive contribution in th report. The physical properties of metals hav hitherto been studied almost exclusively on accou of their technical importance, and the purel scientific aspect has remained comparativel barren. The term 'metallic state' includes bodi in which the binding forces may be homopolar ionic: meanwhile, the empirical requirements the metallic bond (which is different from eithe are clearly displayed and their interpretation di cussed. The following paper, by Westgren an Phragmén on alloys, is distinctly illuminating the light of the foregoing.

Experimental and instrumental interests a represented by the two-circle spectrometer due Dr. Wooster, and the integrating microphotomet for which Mr. Astbury is responsible.

Part 4 consists of a group of papers of a mo general character (Kolkmeijer, Mark, Mölle Porter, Reis, Weissenberg), which produced at th meeting a lively exchange of views. Prof. Ewa brings the formal contributions to a close mo

appropriately with a masterly account of the new Heitler-London theory of chemical combination. That aspect of quantum conceptions most readily approached by the theory of groups finds a natural place alongside the labours of the practical crystallographer.

Just over forty years ago (May 1889) Mendeléeff expressed his ideal in the words: "To hasten the advent of true chemical mechanics." Here is a collection of papers which constitute no mean step towards that goal.

F. Ian G. Rawlins.

The Nature of Epidemicity.

The Genesis of Epidemics and the Natural History of Disease: an Introduction to the Science of Epidemiology based upon the Study of Epidemics of Malaria, Influenza, and Plague. By Lieut.-Col. Clifford Allchin Gill. Pp. xxvi + 550. (London: Baillière, Tindall and Cox, 1928.) 21*s.* net.

THE prevalence of many infective diseases in epidemic form—by which is meant a sharp increase in incidence over a short period of time—is a problem the solution of which has exercised many minds since the times of the medical philosophers of ancient Greece. Many of the hypotheses formerly advanced have been found to be inconsistent with increasing medical knowledge, and there is no unanimity of opinion among epidemiologists concerning those that have survived. Only a careful collection and unbiased analysis of all the factors and data, together with the vision to interpret them, is likely to unravel the tangled skein.

Lieut.-Col. C. A. Gill, Director of Public Health in the Punjab, has now ventured into this 'no man's land' and has produced an impressive book, the outcome of a painstaking study of epidemics over many years, in particular of malaria. The subject matter is presented in five parts. The first part commences with a statement of definitions, which are particularly good, proceeds to survey ancient and modern hypotheses regarding the cause of epidemics and the methods of epidemiological research, and concludes with a presentation of the author's hypothesis of the nature of epidemicity. In Part 2, the known facts respecting epidemic malaria, and also influenza and plague, are stated at length. Part 3 contains a discussion of the general properties of epidemics and a critical analysis of the author's hypothesis. Part 4, entitled "Bionomics of Disease", deals with evolutionary factors and influence of climate in health and disease, and Part 5 contains a general review of the subject, with final reflections. The book is illustrated with charts and maps and a diagram of the endemic and epidemic status of communities.

The varying clinical characters and epidemiological features exhibited by the different epidemic diseases, together with the individuality of their specific parasites, almost inevitably suggest that a dissimilar mechanism is operative in the causation of epidemics. The dominant view at present held is probably that the quality of epidemicity is inherent in variability of the properties of the specific parasite, and that epidemics are the outcome of biological modifications of the latter—the mechanism of epidemicity is essentially an attribute of the specific parasite. Col. Gill, however, brings forward some weighty considerations opposed to this view, and maintains that arguments in favour of a unitary nature of the mechanism of epidemicity are no less formidable. His hypothesis, which he designates the 'quantum theory', suggests that *all* epidemic manifestations consist essentially in a loss of equilibrium between the dose of toxin (or the parasitic factor) and the degree of resistance of the community attacked. The quantum theory postulates

"that all epidemical phenomena are essentially dependent upon a change in the relationship of the infection quantum and the immunity quantum. It ascribes the precise cause of 'loss of equilibrium' between 'infection' and 'immunity', primarily and predominantly, to an increase of the infection quantum—the essential factor in the causation of epidemics is of a quantitative rather than a qualitative character. . . . An epidemic is thus regarded as mainly the outcome of a quantitative change of the transmission factor and the immunity factor, and the intensity of epidemics is held to be a function of the range of amplitude of these factors, which in turn is attributed to the influence of climatic conditions in determining a great and sudden elevation of the infection quantum and a corresponding depression of the immunity quantum."

The arguments presented in support of this hypothesis are skilfully marshalled and are mainly based upon a consideration of malaria, plague, and influenza. It must be left to the statistician to evaluate the precise significance that can be attributed to some of the figures adduced, but in the case of malaria and plague, the evidence brought forward seems strongly to support the author's hypothesis. As regards influenza, we think he is on more debatable ground and the evidence is perhaps less convincing, though this may be more the fault of the extreme complexity of the influenza problem.

Recent studies on diphtheria, which, though not

quite comparable to the diseases discussed, shows periods of epidemic prevalence, tend in one respect to support the author's hypothesis, for it has been shown that the parasitic factor, the diphtheria bacillus, exhibits a remarkable degree of constancy as regards virulence—that is to say, it presents little variation qualitatively. The studies of Sir Leonard Rogers on cholera and other diseases also support the hypothesis of the close relationship between climatic conditions and the occurrence of epidemics.

The author appears to ascribe more importance to an increase in the amount of infection relatively greater than the depression of communal immunity in the genesis of epidemics, but it does not seem clear upon what grounds. In the case of diphtheria, and also of measles, the evidence appears to us to be in favour of depression of immunity being the more important factor. These, however, are side issues, and the author would be the first to admit that he has been able to adduce few certainties. He has undoubtedly produced a work of considerable importance and a hypothesis which deserves the careful consideration of epidemiologists. R. T. H.

Progress in Psychiatry.

Recent Advances in Psychiatry. By Dr. Henry Devine. (The Recent Advances Series.) Pp. x + 340. (London: J. and A. Churchill, 1929.) 12*s.* 6*d.*

DURING the post-War years, and more particularly since the Royal Commission on Lunacy completed and published its labours, the subject of mental disorder has been one of universal public interest. Dr. Henry Devine, the superintendent of the Holloway Sanatorium, was entrusted with the work of writing the volume in Messrs. Churchill's well-known "Recent Advances" series dealing with this subject.

Dr. Devine has carried out what proved to be a very difficult task with extraordinary thoroughness, and is to be congratulated on a very fine piece of work. Anyone conversant with the extent of the field in mental disorder and its cognate subjects will marvel at the success which has crowned the author's effort to cover as much of the ground as possible. He is careful to emphasise what is perhaps one of the most important attitudes towards mental disorder, namely, that no single etiological factor, in practically all instances, is sufficient to account for the disease. In all cases there are at work closely inter-related mental and physical causes—mental stress, acute or chronic, on one hand, and heredity, focal infection, organic disease and disorder of the internal secretions, on the other.

After a well-balanced discussion of the basis of psychiatry, the author divides the rest of his book into five parts. The first part deals with toxic, infective, and somatic factors in the causation of mental disorders. In this section he discusses the very important subject of the effect of toxic agents on the germ plasm, and concludes that there is a very close relationship between hereditary disease and a psychopathic predisposition. At the same time, he is careful to emphasise the very great importance of focal infections in all parts of the body as causative agents. The important fact is that in the majority of cases these infections are not discovered except by highly skilled biochemical and bacteriological work. This point cannot be emphasised too strongly. Physical examination of a patient by the family doctor is quite insufficient; it is work for highly skilled research workers, of which there are far too few in Great Britain.

In the second part, Dr. Devine discusses the development of what is commonly known as protein shock treatment and other similar forms of treatment, leading up finally to the now almost universal treatment of that most fatal of maladies, general paralysis of the insane, by benign tertian malaria. The author gives a well-balanced account of this most interesting department of therapeutics. In the third part, he discusses the various biochemical and physiological aberrations which are to be found in mental disorders. Perhaps the most important subject in this section is the work of Golla on the physiological investigation of pleasure and pain and of the neuroses. In the fourth part, he discusses what is one of the most recent and most interesting developments of modern psychiatry—the influence of physical and psychological types.

In the fifth and last part, the author deals with the purely mental aspects of mental disorder in a reasonable and impartial manner. Into this section he brings the important work of Pavlov on conditioned reflexes. The chapter entitled "The Morbid Mind" is the best chapter in the whole book, and one from which every morbid and every normal mind would gain great benefit by reading. Dr. Devine wisely points out that psychotherapy is of very limited use in the treatment of the insane except in the direction of occupational therapy and the attitude of the mental nurse, which are really indirect or environmental forms of psychotherapy.

This book will remain a standard record of progress in a branch of medicine which is all too frequently adversely criticised by the public.

Our Bookshelf.

Methodik der wissenschaftlichen Biologie. Herausgegeben von T. Péterfi. Band 1: *Allgemeine Morphologie.* Pp. xiv + 1425. Band 2: *Allgemeine Physiologie.* Pp. x + 1219. (Berlin: Julius Springer, 1928.) 188 gold marks.

The aim of the editor and his forty-two expert collaborators has been to produce an account of the most trustworthy methods which have been employed in biological investigation. The first volume opens with an introduction to the mathematical treatment of biological questions including graphic methods, and this is followed by chapters on microscopical optics, including measuring, drawing, polarisation and ultramicroscopy, on vital staining, tissue culture, microdissection and microisolation, and on the methods for making permanent preparations and sections. The next part, on cytology, by Dr. K. Bělař, is noteworthy for the lists of the most suitable animals and plants for the study of cytoplasm, and in the succeeding part on methods for the examination of Protozoa he is equally helpful in indicating the most suitable examples for study. Chapters follow on histological and histochemical methods, on embryological and anatomical material, and on the microtechnique of invertebrates.

In the second volume the opening chapters on zoological and botanical museum technique are followed by others on the collection of living animals of various groups, and the keeping of them in fresh-water or sea-water aquaria, or in vivaria; special attention is devoted to insects (with an appendix on Lymantriidæ and Saturnidæ) and to mammals. The culture of algæ and fungi, and the keeping and rearing of higher plants as objects for the study of heredity or for physiological work, are considered. Excellent accounts are given of methods of illustration for natural history purposes by photography, microphotography, and kinematography. A chapter follows on variation, correlation, proving the agreement between empirical and theoretical figures, the analysis of inheritance factors, etc. The developmental mechanics of plants and of animals, including methods of artificial parthenogenesis, and the more important physiological methods as applied to animals and plants, are the subjects of the concluding chapters. An appendix gives technical names in German, English, French, and Italian.

This is a valuable work of reference for biological laboratories; advanced students and investigators who turn to it will find helpful information and suggestions over a wide range of biology, and the list of published works at the end of each section directs the reader to memoirs with further details. The chapter on the collection of living animals deals only with fresh-water and terrestrial examples; some account of the methods of collection of the more important marine animals would have been welcome.

The work is excellently produced and each volume has a good subject index.

(1) *The Excavations at Ur and the Hebrew Records.* By C. Leonard Woolley. Pp. 61. (London: George Allen and Unwin, Ltd., 1929.) 2*s.* net; paper, 1*s.* net.

(2) *Biblical Anthropology compared with and illustrated by the Folklore of Europe and the Customs of Primitive Peoples.* By the Rev. H. J. D. Astley. Pp. vii + 262. (London: Oxford University Press, 1929.) 12*s.* 6*d.* net.

(1) Those who know Mr. Leonard Woolley's "Sumerians" will turn with interest to his Arthur Davis Memorial Lecture on the bearing of his discoveries on Biblical history. Mesopotamia is, of course, a long way from Palestine, and "the periods with which we have to deal are sometimes far removed in time from those which interest most the Bible student", yet the link is there. The two points of contact which concern us most would seem to be the flood narrative and the story of Abraham. Of the first we read that "such archæological data as we possess, and the traditions of the Sumerians themselves, are most easily explained and best reconciled by the assumption that the Flood was the epoch-making historical event which they believed it to be". As for Abraham, the chief point of interest is that "living at Ur, so far from being a primitive Bedouin accustomed only to the wide spaces of the desert, he was the heir to an age-old civilisation sharing the complex life of a great trade centre". Another interesting point is that "it would not be even fanciful to hold that Jacob's dream was based on tales he had been told of the ziggurat of Ur, where on festivals the priests went in procession up and down the long stairways which led from earth to Heaven".

(2) The comparatively new science of anthropology, or the study of man apart from religious and cultural prepossessions, has also shed much light on story and custom in the Bible, as Sir James Frazer's monumental "Folk-lore in the Old Testament" has shown. Canon Astley's book is in part a collection of articles contributed to such periodicals as the *Hibbert Journal* and the *Modern Churchman*, and should prove most interesting material for the Biblical student who is fascinated by anthropological parallels between what he finds there and religious custom in other parts of the world.

J. C. H.

Colloid Chemistry. By Prof. The Svedberg. Second edition, revised and enlarged in collaboration with Arne Tiselius. (American Chemical Society Monograph Series, No. 16.) Pp. 302. (New York: The Chemical Catalog Co., Inc., 1928.) 5.50 dollars.

The first edition of this book was reviewed in these columns in 1924, and this new edition is a revised version with some fifty pages of additional matter. The original scheme of the book, in so far as relatively greater space is devoted to the author's own investigations, is retained, and in consequence there is a freshness and reality in presentation which a mere compilation so frequently lacks. The amendment of the old text has been thoroughly carried out, and the strange method of printing some of

the formulæ has been avoided; crude or inconvenient methods of investigation have given place to better ones wherever the latter have been devised.

The work of the author on sedimentation equilibria with the ultracentrifuge has carried this method of attack on the problem of the size of colloid particles into realms hitherto undreamt of, and those who desire a concise and readable account of this fundamental work will find it here. The extension of the investigation from the inorganic sols, to which it was first applied, to colloids of biological interest, has resulted in the determination of the molecular weights of the latter, which hitherto had been found only in a few cases by more tedious methods. New work in ultramicroscopy, in the technique of measurement of diffusion and cataphoresis, and in the application of X-ray analysis to the study of sols and gels, has been carefully incorporated. No chemists or physicists interested in colloids should miss reading this book, even if they have already enjoyed the first edition.

P. C. L. T.

Comparative Vocabularies of Bushman Languages. By D. F. Bleek. (University of Cape Town: Publications of the School of African Life and Language.) Pp. vi + 94. (Cambridge: At the University Press, 1929.) 7*s.* 6*d.* net.

IN this volume, Miss Bleek has worked on eleven vocabularies, the materials for which for the most part have been collected by herself at one time or another. In her previously published study of the Naron she gave a preliminary account of the classification of Bushman languages which is here elaborated. The languages are divided into three groups, of which six belong to the southern group, three to the northern, and two to the central. The groups differ in the characteristic clicks and in change in root and grammar, especially the last. In the introductory section which deals with the peculiar features and characteristics of the groups, Miss Bleek has analysed Bushman physique and culture with the view of a possible coincidence in distribution of language and race. The smallest average in height is found in the southern group. As regards culture, all Bushmen live in bush huts, and are hunters and collectors of food. The Hottentots, who have taken to a pastoral life, used huts in the old days, but they differed from those of the Bushmen in being made of reed mats and not bush. The clothes of all Bushmen are similar, a leather loincloth and small kaross. The ancestors of the southern group painted and engraved in stone down to a recent date, but have now lost the art. The general conclusion at which the author arrives is that, while a number of features are common to all, a good many differences in custom coincide with differences in speech.

Chemistry in Daily Life. By Dr. Samuel Glasstone. Pp. vi + 250. (London: Methuen and Co., Ltd., 1929.) 6*s.* net.

DR. GLASSTONE'S book is of a type which should be very welcome. It deals with a number of aspects of chemistry which are of interest in daily life, and each chapter concludes with a few questions, som subjects for essays and discussion, suggestions fo further study, books to read, and suggestions fo experiments. The contents are based on a cours of extension lectures and some B.B.C. broadcas talks, and the style and choice of material are bot excellent.

The author expresses the hope that the book wil be found of interest to the general reader, useful a a basis of extension and similar lectures for adults and suitable for use in schools, whether chemistr is taught or not. There can be no doubt that i will fulfil all these requirements satisfactorily. Th information is generally accurate, and the treat ment is more detailed than usual in books of thi type, so that even advanced students will find muc that is new to them. Symbols and formulæ ar used. The least satisfactory parts are some o those dealing with the early history of chemistry On p. 5 the really valuable contributions to ex perimental chemistry made by the Alexandria chemists are not given proper credit, and on p. 8 it is stated that there are representations of glass blowers on Egyptian inscriptions so far back a 3000 B.C. These are minor faults and the boo may be strongly recommended.

Lumineszenz-analyse im filtrierten ultraviolette Licht: ein Hilfsbuch beim Arbeiten mit de Analysen-Lampen. Von Prof. Dr. P. W. Danck wortt. Pp. vi + 106 + 16 Tafeln. (Leipzig Akademische Verlagsgesellschaft m.b.H., 1928 6·50 gold marks.

THE main subject matter of this little book ha become familiar to most workers in practical science even if only by witnessing a few fascinating demon strations at some conversaziones. Most of thes can be repeated with some form of the well-know tent or camera, open and curtained in the front, i the roof of which is concealed a quartz mercur burner; the light is filtered through a 'sky-light of Wood's glass, which allows only the ultra-viole rays to fall on the object placed on the floor of th tent. While such phenomena appeal to the lay man, they open up a far wider field to the imagina tion of the scientific worker and the technologis and the object of this handbook is to broade the horizon and lure the reader to explore muc further by pursuing observations in his ow laboratory.

The invitation is irresistible to the chemist, th mineralogist, the pharmacist, the toxicologist, th biologist, and the industrialist, who may differen tiate between substances so closely allied that the are in ordinary practice indistinguishable eith chemically or physically, for example, olive oil different grades; or between substances essentiall different although similar in appearance, such a a normal paper and the same after acetylation.

Of the forty illustrations one may be selected- the fluorescent structures in the sporangia of a fe are revealed in striking contrast, whereas all appe similar in daylight. The book is well written an well produced; while its value is enhanced by comprehensive, classified bibliography.

Letters to the Editor.

The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*]

Natural Selection.

IN NATURE of June 8 there appears a letter from my friend Prof. Poulton in which he replies to my statement that 'natural selection' affords no explanation of evolution. He quotes *in extenso* a letter from Darwin to the distinguished American botanist Asa Gray, in which Darwin endeavours to deal with the objection that natural selection is a truism and that variations are produced by definite causes and are not due to 'chance'. Darwin compares the action of natural selection to that of a man building a house from stones of all shapes found at the foot of a precipice on a mountain-side. The shapes of these stones, he says, would be due to definite causes, but the uses to which the stones were put in building the house would not be explicable by these causes.

Of course, when I wrote the statement which Prof. Poulton criticises, I was well acquainted with this letter of Darwin. Prof. Poulton quotes it with the same reverence as our fathers used to quote a passage from Holy Writ; but a false analogy and piece of thoroughly bad reasoning seem to me to be as worthy of censure when the author is Darwin as they would be if the author were one of his religious opponents.

A little reflection will show the fallacy in Darwin's argument. That the shapes of stones on the mountain-side are due to definite causes is obvious to anyone who has ever compared a scree on a hill-side of Harlech grits with one on a hill-side of Llanberis slates—to go no farther away than Wales for an example. But when a man begins to build a house, we have the intervention of a *definite purpose* directed towards a *fixed end* and governed by a *clearly-conceived ideal*—and it is doubtless true to say that these psychic factors have no conceivable relation to the causes which produced the stones.

'Natural selection' means, as I said before, merely that a creature survives in a given environment; as to why it survives, or whether its survival be due to one character more than another, and as to how it acquired that character, the theory gives us no information whatever. The supporter of the 'mimicry' theory, when he finds one insect superficially resembling another belonging to a different family or order, *assumes* that it is because of this resemblance that one of the insects survives. It may be so, but there is no proof that it is so; it ignores the fact that the most marvellous resemblances often occur between insects belonging to different orders *inhabiting different countries.*

The supporter of evolution by 'natural selection' further assumes that the insect which survives is one of a large number of differing types produced by 'variation', that is, 'chance', which happened to fit the environment, and that all the others perished. This, again, is an unsupported assumption; in fact, one may go further and say that it is definitely not true. When in the wild we meet, as we occasionally do, with ill-adapted types such as albinos, melanics, etc., they belong, as Uexküll has well said, not to the *natural*, but to the *pathological*. Darwin, through constant usage, had grown to personify natural selection, and sub-consciously to regard it as a purposeful agency. It became a habit, and was shared by his family. I have even heard one of them talking of the 'mistakes' made by 'natural selection'. The whole mental attitude is a first-class example of the error due to what McDougall calls the "reification of words".

That when a species of animals is examined a general type can be discriminated and that individuals deviate slightly from this type, no one would deny. But to what are these deviations due? Even Morgan admits that they are due to the environment, "for there is no other source for them". Did Darwin, then, mean to say that the changes produced in a creature by the environment have no relation to its survival in that environment? If he did so, is it not obvious nonsense? No! There is no escape from the dilemma so ably posed by the late Dr. Bateson: "Either variation is due to chance or to the reaction of the animal to the environment".

That natural selection is a reality no one, who like myself has for the last seventeen years raised annually thousands of larvæ of the same species, would doubt for a moment. But what is 'selected' is not the 'random' variation but, as Kammerer has well put it, "the most plastic individual", that is, the one which reacts best to the environment; in other words, *the most vigorous*. As to why individuals of the same brood differ from each other in vigour we do not fully know, but we are beginning to get glimmerings of the reasons. If, for example, we obtain eggs from a sea-urchin at the end of the season, these eggs, though to all appearance ripe and normal, are able to give rise only to feeble larvæ which live only a day or two and only complete the early stages of development. Again, it has recently been shown that the position in the ovary of the immature egg has much to do with the vigour of its constitution when ripe and fertilised.

As to attacks of birds on insects, Prof. Poulton has failed to note that I said "serious attack". That birds occasionally attack insects I am well aware. I have myself seen the sparrow, normally a grain-eating bird, chase one of our common cabbage white butterflies, and I have seen some of the jealously guarded treasure of damaged butterfly wings which Prof. Poulton has collected after a search of many years. But that butterflies are subject to such decimating attack that the occurrence or absence of a patch of colour means life or death there is no evidence whatever.

I have written at some length on the subject, because, although I recognise that the facile truism of 'natural selection', so easily grasped by the uncritical mind, did succeed in making mankind believe in evolution, yet now I am convinced that the view that 'natural selection' explains evolution is one of the greatest hindrances to biological science. It leads to unsupported hypotheses, and to facile teleological explanations which dispense with and discourage research into the functional significance of the organs of animals. Why has an animal got a particular pattern or shape? Because it has been developed by 'natural selection' in order to enable it to escape its enemies! With this explanation too many biologists are content. "Verily all things are possible to him that believeth."

Super-cooled Water.

IN a recent letter to NATURE (Feb. 16, p. 244) I directed attention to Beilby's observation that water drops become hard when chilled to − 12° C., and to the fact that water is quite fluid at − 9·3° (White and Twining, *Jour. Am. Chem. Soc.*, **50**, pp. 380-389; 1913). That an important change in properties takes place

between these temperatures is indicated by the difficulty all experimenters have had in cooling water below − 10°. It may be that here the steady expansion which water undergoes below 4° ceases, and that with further lowering of temperature the contraction obtains which was predicted by Bridgman (*Proc. Am. Acad.*, **47**, p. 543; 1911–12). Water has been cooled in capillary tubes to − 18·5° (T. Borovik-Romanova, rev. in *Chem. Abs. Am. Chem. Soc.*, **19**, p. 3186; 1925), and as fine drops suspended in oil to − 20° (M. L. Dufour, *Arch. Sci. Geneva*, **10**, p. 350; 1861), but no information is given as to the physical state at these temperatures.

Two observations may be cited which are difficult to fit in with the result obtained by Beilby. Crystallisation of super-cooled water may be prevented either by keeping it perfectly still or by rapid movement, and R. Pictet cooled water to − 19° by subjecting it to constant agitation (*Arch. Sci. Geneva*, **1**, p. 498; 1878). Mousson found that a copper rod passed through a column of ice when it was under the melting pressure at − 18° (*Pogg. Ann.*, **105**, pp. 161-174; 1858). Thus, if water becomes glassy at − 12°, we have the surprising result that vitrification can be prevented by movement of the liquid, and that under great pressure the glass is liquefied.

By the kindness of the Union Cold Storage Company, observations were made at their Cannon Street stores in a chamber the temperature of which was on one occasion − 17° and on another − 22°. Drops of water at + 15° were chilled by contact with a glass slide. The larger drops crystallised to form negative spherulites, but smaller ones averaging 1 mm. to 2 mm. in diameter remained isotropic. When a steel point was brought sharply down on to the drops, they crystallised with an audible click: the point did not penetrate the drops and the inference is that they were hard. The possibility must be considered, however, that the velocity of crystallisation is so great that it is ice which is being tested and not water. Walton and Judd have found that the linear velocity of crystallisation increases with super-cooling and is 11·4 cm. per sec. at − 9°. They were unable to determine the temperature and value of the maximum velocity owing to the spontaneous crystallisation which occurred below − 9° (*Jour. Phys. Chem.*, **18**, p. 722-728; 1914).

Apart from its intrinsic interest, definite knowledge of the physical state of water would be valuable in the application to ice of those theories of solid structure and flow which are based on the conception of a liquid cement binding the grains of the aggregate together, and on the production of liquid at the surfaces of slip. The subject is also of interest in view of the fact long known and recently so conclusively demonstrated by Köhler ("Untersuchungen über die Elemente des Nebels und der Wolken", *Akad. Abhandl.*, Stockholm, 1925) that clouds at temperatures down to − 28° (at least) are composed of water drops. It may be noted here that the deposit on the cooling pipes at the Cannon Street stores was found to be a mixture of water drops and ice—this at − 22°. Direct passage from the vapour to the vitreous state has been obtained in other substances than water, and sudden vitrification with falling temperature would be in accordance with the general behaviour of super-cooled liquids. E. Berger has directed attention to the similarity between the glasses and water, in that with super-cooling a relatively rapid increase of viscosity takes place (*Glastechn. Ber.*, **5**, pp. 399-400; 1927).

That vitrification should be prevented by movement or pressure, however, is so anomalous as to call for further examination. I have no opportunity to pursue this work, but it is to be hoped that a careful study of the properties of water below − 10° will be undertaken; the investigation could be most conveniently carried out where low winter atmospheric temperatures are experienced.

Occurrence of Sea Urchins on the Foreshore in Britain.

IN the latest number of the *Journal of the Marin Biological Association* (vol. 16, 1, p. 289), Dr. J. H Orton discusses the occurrence of the common se urchin, *Echinus esculentus*, on the foreshore. In vie of the fact that, in comparison with Plymouth, thes animals can frequently be picked up at low tide a Millport and the Island of Skye, it may be of interes to put on record some observations made by me i August 1923 at Fetlar, in the Shetland Island especially as this island, lying in lat. 60° 35′ N., i some 3° farther north than Skye, from which record by Dr. Lebour are quoted by Dr. Orton.

The shore at Fetlar is for the most part very rock and often precipitous, sometimes with pinnacles juttin out of the water. I can remember picking up *E esculentus* between tidemarks on several occasions i the big sheltered bay, called Tresta Wick, on th south side of the island. Others were obtained fro the sides of the rocky pinnacles just below the wate level, while one was found on the side of the ston steps of the private landing stage. All were appar ently normal and active, and of a large size. So fa as my recollection goes, I do not think they wer discovered at any period of exceptionally low sprin tides.

The temperature of the water was decidedly lo and though I have no exact figures (which coul probably be obtained from the Meteorological Statio at Lerwick), I can vouch for the fact that the wate was sufficiently cold to make shore collecting wit bare feet a distinctly painful process. During th last few days of my stay, the Shetlands were swep by a terrific gale accompanied by very high seas, a the result of which no more sea urchins could b found. Presumably they had either been dislodge by the waves or had migrated to deeper water fo safety.

The fact that the occurrence of *E. esculentus* on th foreshore appears to be more common in the northerl parts of the British Isles than in the south woul seem to emphasise, as Dr. Orton points out, a direc correlation between the temperature of the wate and the life of the animal.

C. C. HENTSCHEL.

Biology Department,
St. Bartholomew's Hospital and College,
London, E.C.1, June 8.

IN the *Jour. Marine Biol. Assoc.*, vol. 16, No. May 1929, Dr. J. H. Orton asks for informatio regarding the occurrence of *Echinus esculentus* abov low water mark on the British coasts. On the nort coast of Scotland I have observed this species a different times of the year. Between April 8 and M of this year, *E. esculentus* was quite plentiful abov low water mark on the rocky shores of the west sid of Loch Eireboll, more especially in the numerou bays and inlets around Rispond, the organisms havin frequently become stranded in the rock crevices as th tide fell. During August and September, on th other hand, this species is not quite so abundan although on many occasions I have captured spec

mens with a landing-net as they retreated down the rocks with the ebbing tide.

I cannot find any reference in my notes to the occurrence of *E. esculentus* on the limestone headland of Heilim on the east side of the loch. This is peculiar because, since the headland is of much eroded limestone affording a fine habitat for a multitude of organisms, I have examined it frequently during low water spring tides.

This would suggest that the nature of the rock—its physical nature or its chemical composition—might be a possible factor affecting the occurrence of *E. esculentus*. This point is being further investigated.

Dinosaurian and Mammalian Remains in South India.

My attention has been directed to an article on "Geological Exploration in India—Dinosaur Remains Unearthed" contributed by Dr. Matley to the *Records* of the Indian Geological Survey, 1929, in which he refers to a preliminary note on the fossil finds from Ariyalur—Trichinopoly Cretaceous area—published by Mr. B. R. Seshachar and myself in the *Mysore University Journal* (vol. 1, No. 2, July 1927). He writes that this party (zoology students) has been "fortunate in finding a number of dinosaurian bones including a vertebra, ilium, scapula, coracoid, head of a humerus, a tooth with a portion of the dentary, and limb bones,

Fig. 1.—Fossil mandible of a carnivore taken in the Ariyalur area.

mostly in a broken condition. This discovery is of importance, as it is the first time that Southern India has yielded identifiable remains of dinosaurs." In the article referred to by Dr. Matley, there is a brief description of the humerus and carpal nodules and a broken amphicœlous vertebra of an ichthyosaurian, besides the ungulate remains of molar teeth of both perisso- and artiodactyles.

A detailed treatment of this interesting collection was deferred with the view of exploring the region more thoroughly, so as to obtain more evidence of the occurrence of the reptilian and mammalian fossils in the Trichinopoly area. In an expedition conducted to this place in December last, we have, in spite of the unfavourable weather conditions prevailing at the time, been fortunate in obtaining some more fossils. Among them we found a portion of a carnivore mandible with the teeth beautifully preserved, a large number of molar teeth of artiodactyles, together with tarsal, metatarsal, and phalangeal bones, humerus and femur, tibia, radius and ulna, scapula and broken specimens of vertebra of both carnivores and ungulates. Our collection is by no means exhaustive, but is sufficient to establish the occurrence of both reptilian and mammalian fossils in the area. I do not propose to deal with the material in this communication, which is merely intended to notify the discovery of an extremely interesting series of fossils in South India, nor do I propose to discuss here the probable theories which have been put forward to account for such occurrence. The photograph of the mandible reproduced as Fig. 1 will give an idea of the condition in which the fossils occur in the Cretaceous area of South India. A detailed description of the material will appear soon elsewhere.

Natural Ionising Radiation and Rate of Mutation.

About a year ago there appeared in these columns a communication by A. R. Olson and G. N. Lewis on natural radioactivity and the origin of species (Nature, April 28, 1928, p. 673), in which it was suggested that the natural ionising radiation of the earth plays an important part in evolution. It was pointed out that the relative effects of rays of different frequency upon the production of variants have not been experimentally ascertained, but that since the rays can only be effective when absorbed, and thus produce ionisation, it seems safe to assume that the various rays will produce biological effects in proportion to the ionisation they cause.

It was our good fortune to discover a location in a street car tunnel in San Francisco, only 15 miles from Berkeley, where the natural ionising radiation is fully twice as great as the radiation in our laboratory in Berkeley. Accordingly, an experiment was planned for the purpose of comparing the rates of occurrence of sex-linked lethal mutations in *Drosophila melanogaster*, following a method already devised by Muller (*Genetics*, **13**, 279-357; 1928) and using a balanced lethal strain synthesised by him.

Up to the present, 5981 individual males have been tested in the first phase of the experiment. Of this number, 3481 tests were made in Berkeley, and 9, or 0·26 per cent, produced no male flies and so revealed the occurrence of new lethals, while 2500 tests were made in the tunnel, and of these 13, or 0·52 per cent, contained no male flies. The difference in rate, $0{\cdot}26 \pm 0{\cdot}11$, while only 2·5 times the probable error, may be fairly significant. When the difference in rate of mutation is computed by a method which analyses the actual experimental variation in rate in the several subgroups in each of the two series (Berkeley and San Francisco), the variation within the series is found to be less than that to be expected in random sampling, so that the significance of the difference between the average rates for the two locations is increased. This difference is $0{\cdot}275 \pm 0{\cdot}086$.

It seems fairly safe to assume, therefore, that the same difference in rate of mutation will continue throughout the remainder of the experiment, in the second phase of which an *X*-chromosome from a normal wild type strain is being tested in alternate generations. This not only doubles the scope of the experiment but also makes it possible to test such lethals as occur in this new chromosome, which it is impossible to accomplish when working with the balanced lethal strain alone.

Even now, however, it seems fairly safe to conclude that the natural ionising radiation of the earth is a very important factor controlling the rate at which

new inherited characters originate in animals and plants. While it may not be inferred from existing evidence that such radiation is the direct cause of mutation, yet a way is now open by which this question can be attacked experimentally. It is our intention to conduct a second experiment which will approximate fairly closely to the requirements of a crucial test of this important question.

Mammalian Life in High Latitudes.

How far seals and whales migrate north in the summer months is a moot question, but the following facts suggest that the latitude reached in the case of the floe-seal, the narwhal, and the Greenland whale is a high one.

The occurrence is recorded, in log-books of whaling vessels in my possession, that in the Greenland Sea, in lat. 80°—a situation in which, owing to the direction of the prevailing winds, the ice is usually drifting south—in May of numbers of floe-seals—seals which, as Stefansson explains in his "Friendly Arctic", are tied to sheets of ice, of moderate thickness, the product of a single winter's frost, which therefore must have drifted south from a higher latitude during the winter and early spring. For example, on May 27, 1887, lat. 79° 58′ N., long. 3° E., "got into a Floe-water; some Narwhals and many floe-seals".

The occurrence is also recorded in my father's log-books, that in the Greenland Sea, in lat. 80°, in May, large numbers of narwhals were often seen going north-east and in the direction of the high latitude in which the observers in the *Fram* saw them. Example, May 28, 1887, lat. 80° N., long. 2° E., "Numbers of Narwhales passed us during the night; all going north-east".

The Greenland whales, with the exception of a few old ones, mostly males, which in some seasons were seen off the Greenland coast in the summer months, deserted the waters between Greenland and Spitsbergen in June (in late seasons, not until July) and were not seen again by the whalers until the following spring. As Scoresby says: "It has often happened that not a single whale has been seen by any individual belonging to the whole Greenland fleet after perhaps the middle of June". They disappeared going north-west, but how far they went in that direction the whalers, being unable to follow them, never knew. Example, July 7, 1876, lat. 78° 40′ N., long. 2° W., "Saw a whale . . .; whale (the last one seen that season) making much headway to north-west".

The Greenland whale appears also to make the Arctic Ocean its usual breeding place; the fully grown whales that Scoresby speaks of seeing in latitude 80°, in the spring, which disappeared by the end of April, might quite well have been pregnant females on their way to produce their young in the Arctic Ocean. As mentioned in my letter on the "Breeding Habits of the Greenland Whale" (NATURE, April 13, 1929), Greenland whales were seldom seen in the Greenland Sea with calves with them, and then usually in the spring, in lat. 79° or 80°, on the confines of the Arctic Ocean. That they did have calves was proved beyond a doubt, as my father says, by the numbers of young whales that were frequently seen.

It seems also worth while pointing out that each of the Greenland whale's haunts communicates with the Arctic Ocean and that they migrate towards it in the spring: the whales of the Bering Sea going north through the strait of the same name, those of the Greenland Sea north through the strait between Greenland and Spitsbergen, and those of Davis Strait and Baffin Bay west through Lancaster Sound, etc. Lastly, in the Antarctic, where there is no polar ocean to which it can retreat in the summer months it is absent.

ROBERT W. GRAY.

The Origin of Alphabets.

THE mouth gesture theory of human speech—of which a summary appeared in NATURE of Feb. 23, p. 281—has just received a further extension which may be of anthropological and psychological interest.

The basis of the main theory was:

(1) That man naturally and unconsciously tends to express his ideas in pantomime.

(2) That there is a natural and unconscious sympathy between bodily gesture—more particularly hand gestures—and movements of the mouth and tongue.

In this way, it was suggested, the primitive panto-mimic code of human expression became associated with a related code of unconscious mouth gestures which resulted in the production of the various speech sounds, and their use in the form of language.

Let us consider what might be expected to happen when—after a million years or so of speech development—man began to feel the need of a method of recording his speech. It is obvious he could not attempt to record its sounds, and *ex hypothesi* he could not directly record its gestures, for he was unconscious of them. Under these conditions it seems likely that the original sympathy between hand and mouth became once more operative, but in the reverse direction.

Man's mouth, by this time, had established a well-defined code of gestures by which his ideas could be expressed. His hand was now searching for a new form of symbolism by which to record his speech. This symbolism was one of hand gestures, which were made to leave their track on the surface of stone or bark or plastic clay; these were (still unconsciously) inspired by the mouth gestures for which they stood.

Human writing admittedly derives originally from pictographs, that is, hand gestures which outline the form of the object or motion described, but except in the case of the ideographic scripts, such as Chinese, the development of writing has tended to be largely phonetic—either syllabic or alphabetic. In other words, the system has tended to be one of hand gestures which symbolise mouth gestures.

Granting that the words for natural objects would most simply be recorded by outlining the objects themselves, as in pictography, there must have been an early need for a method of recording speech sounds *per se*. I have recently found definite evidence that in Sumerian, and still more in Greco-Roman writing, the symbolism depended largely on the principle of unconscious imitation of mouth gestures.

Thus, in the case of the Greek alphabet:

B represents an outline of the two lips of a head facing to the right; Θ is a front view of a mouth showing the tongue between the teeth; Δ is a view of the tongue raised to the palate, as in articulating the consonant D; Λ is a similar gesture, but made more lightly.

Mr. H. B. Walters, of the British Museum, whom I have consulted on the matter, agrees that nearly all the letters of the Greek alphabet show influence of

mouth gestures. I may add that more than twenty of the letters of our own alphabet still show the same influence.

The evidence on which the theory rests will be published elsewhere. R. A. S. PAGET.

Natural History and Folk-Lore.

DR. W. MALDWYN DAVIES'S reference (NATURE, July 13, p. 55) to 'gwas-y-neidr'—the Cymric equivalent of 'ether's mon'—as the name for a dragonfly reminds me that 'gwas-y-neidr' is a not unusual folk-name for the yellow-hammer, although perhaps the bird is more often called 'pen-felen' (= yellow-head). In 1914 I was at Nevin, Carnarvonshire, where a man, about forty-five years of age, asked me if I thought that the 'gwas-y-neidr' was really poisonous. He went on to explain that as boys his companions and he always smashed the eggs of the yellow-hammer if they found a nest, and that when in winter they caught small birds in his father's farm-yard, the yellow-hammers were always killed with a stick, as it was considered dangerous to touch them with a naked hand. The birds had been hatched from eggs laid by adders and the serpentine markings on the eggs in the yellow-hammers' nests were evidence of their reptilian origin; markings which elsewhere have earned for the yellow-hammer the less sinister names of 'writing master' and 'scribbling lark'.

What was substantially the same story was told by peasants and fishermen in other places in Lleyn, and since then I have met with 'gwas-y-neidr' in other parts of Wales, the bird always being associated, to its detriment, with the adder. At St. David's and at Fishguard, Pembrokeshire, the adder is by some reputed to go into the nest of the 'gwas-y-neidr'; others say that the bird carries food to the adder; and one man told me that he always destroyed the eggs in order to save them from the adder. At Newcastle Emlyn, Carmarthenshire, the 'gwas-y-neidr' is said to warn the adder by its notes of the approach of an enemy.

Dr. Davies cites 'gwas-y-gog' as a Welsh name for the hedge-sparrow. Personally, I have never heard it applied to that bird, but it is a common folk-name for the meadow-pipit, the most frequent fosterer of the cuckoo (gog) on the Welsh moorlands, where the feeding of a young cuckoo by meadow-pipits is a familiar sight in July and August. The name is a singularly apt one, by reason of the unwearying ministrations of the duped pipits which are evoked by the peremptory and incessant hunger-cries of the cuckoo.

CHAS. OLDHAM.

The Bollin, Shrublands Road,
Berkhamsted, July 23.

IN reference to Dr. R. J. Tillyard's letter in NATURE of June 1 and succeeding letters in the issues of June 15 and July 13, concerning the dragonfly's being called the 'ether's mon' or 'adder's servant', I may add that in the coal-field districts of South Wales, when I was a boy, we used to call the dragonfly the 'gwas-y-neidr', or 'servant of the snake', and the tradition was that where the dragonfly was seen above the grass, the snake would be found below.

Obviously this would be a likely event if the 'nader' (snake) were the common grass snake, which like the dragonfly frequents marshy meadows and the water-side, but if 'nader' is translated 'adder' or 'viper' in the modern scientific sense, the association of fly and snake would be accidental at best.

The fact that the tradition exists in the rather isolated valleys of the Welsh mountains and in the Welsh language in precisely the form given by Dr. Tillyard in English, suggests that the legend may be of very ancient origin. L. ROWLAND.

Second Spark Spectrum of Selenium (Se^{++}).

THE spectrum of selenium obtained by the condensed discharge is much more complicated than that of sulphur under the same condition of excitation. Of the existing data on the subject, Misserschmitt's list of lines given in vol. 6 of "Handbuch der Spectroscopie" by Kayser and Runge appears to be fairly complete, but the abundance of lines in his list and inaccurate values of their intensities were rather perplexing. Bloch's recent record of a few Se^{++} and Se^{+++} lines (*Comptes rendus*, T. 183, p. 762), and the photographs obtained in this laboratory with a prism spectrograph and a ten-foot concave grating under varying conditions of excitation, have been found to be promising in sorting out lines of Se^{+}.

Taking the structure diagram of Se^{++}, the possible transitions are

$$2N_2 \swarrow N_2N_3 \quad \leftarrow N_2O_2 \swarrow N_2O_3$$
$$\qquad\qquad \nwarrow N_2O_1 \qquad\qquad \nwarrow N_2P_1$$

By the application of the extension of the irregular doublet law given by Saha and Kichlu combined with the method of horizontal comparison described by Saha and Majumdar, *PD*, *PP*, and *PS* groups of $N_2O_1 \leftarrow N_2O_2$ were located graphically at 24000, 28000, and 28400 respectively.

Leading lines of these multiplets in the same transition are:

$$^3P_2 - {}^3D_3 = 23979 \quad (\lambda = 4169{\cdot}16)$$
$$^3P_2 - {}^3P_2 = 27482{\cdot}6 \ (\lambda = 3639{\cdot}6)$$
$$^3P_2 - {}^3S_1 = 28210{\cdot}0 \ (\lambda = 3643{\cdot}8),$$

the term differences being

$$\Delta P_{01} = 450, \ \Delta P_{12} = 949, \ \Delta D_{12} = 187, \ \Delta D_{23} = 446.$$

A full description of this analysis will appear along with that of Se^{+}. D. K. BHATTACHARJYA.

Department of Physics,
Science College, Patna,

Spectrum of Doubly Ionised Arsenic.

THE deepest term of the separation of doubly ionised arsenic (As III) is $4p\ ^2P_1$. The values of these doublet terms relative to ^2G were reported in a recent paper (*Ind. J. Phy.*, **5**, 3, p. 3) to be 220, 221 cm.$^{-1}$. It was found in the course of this work that a number of lines that could be attributed to doubly ionised arsenic remained unclassified. The spectrum has been further investigated. About forty-five of these unclassified lines have entered into quartet systems, the terms identified being:

$5s'\ ^4P$; $5p'$ (^4P, ^4S, and ^4D) and $5d'$ (^4D and ^4F).

It is found that

$5s'$, ^4P	separations are	2133 and	1062
$5p'$, ^4P	,, ,,	1324 and	737
^4D	,, ,,	1429 and	793 and 432
and $5d'$, ^4D	,, ,,	1283	749 and 367
and ^4F	,, ,,	850	367 and 124.

Decay Problems in Mathematical Physics.

CONSIDER a quantity u, satisfying the equation :

$$L(u) = \rho \frac{\partial^2 u}{\partial t^2} + w \frac{\partial u}{\partial t}, \quad . \quad . \quad . \quad (1)$$

in a closed finite space, with any homogeneous boundary condition at the boundary of the aforesaid space.

Here L is a linear differential operator of the second order, extending to any number of dimensions ; for example, for three dimensions :

$$L(u) \equiv \frac{\partial}{\partial x}\left(p\frac{u}{\partial x}\right) + \frac{\partial}{\partial y}\left(p\frac{\partial u}{\partial y}\right) + \frac{\partial}{\partial t}\left(p\frac{\partial u}{\partial t}\right) - qu,$$

whereas ρ and w are finite and positive functions of the independent variables entering in L.

Then the following theorem has been proved : If a system at rest, the free motion of which is described by (1), is acted on by an oscillatory force of frequency large with respect to the lowest natural frequency of the system, until the stationary state is reached, the time of increase is directly proportional to the whole absorption and indirectly proportional to the volume, but independent of the shape of the system and of the places of the experimenter and the force. If the force, after the stationary state is reached, stops abruptly, the time of decay obeys the same law. Moreover, the increase is complementary to the decay, the sum of the amplitudes at a time t, measured from the moment the force starts in one case and from the moment the force stops in the other, being constant and independent of t.

This theorem may immediately be applied to the theory of electromagnetic radiation in closed spaces and to the acoustics of large rooms. In both cases it gives the time required by the system to reach the stationary state after a change of the radiating forces.

It has been verified experimentally by W. Sabine in the acoustics of large rooms ("Collected Papers on Acoustics", p. 39), whilst experiments by Dr. Zwikker in this laboratory have shown that the complementary nature of increase and decay really exists.

An extension, comprising absorption w, which depends on the frequency, but in a bounded and for high frequencies slowly variable way, may easily be proved.

For details reference is made to a paper, entitled : "Über das Dämpfungsproblem der mathematischen Physik", which will be published in the *Mathematische Annalen* and to a paper entitled "On the Acoustics of Large Rooms", which will appear shortly in the *Phil. Mag.*

Raman Effect in Gases and Liquids.

IN a note recently communicated to NATURE it was pointed out that the Raman effect in triatomic molecules having a linear model could be explained on the assumption of a fundamental mode of vibration along the line joining the three nuclei of the molecules. Such vibrations take place along the direction of propagation of the radiation and behave as optically inactive ones and are not manifested in the near infra-red bands. The case of carbon dioxide was discussed on this basis.

The Raman effect of liquid carbon disulphide has recently been studied in Sir C. V. Raman's laboratory, and it shows two prominent modified lines due to absorption of energy corresponding to infra-red wave lengths 12·5 μ and 15·27 μ (private communication), which have so far not been observed as absorption bands. This can now be explained on the supposition of an optically inactive frequency $\nu = 728$ cm.$^{-1}$ of $\lambda = 13{\cdot}73$ μ. The two lines being due to transitions $\Delta i = \pm 1$ of the molecule (*Nat. Research Council Bull.*, **57**, p. 62) from this fundamental vibrational state.

The observations of McLennan and McLeod (NATURE, Feb. 2, 1929) regarding the Raman effect in liquid oxygen, nitrogen, and hydrogen, showing the absorption of energy corresponding to values of $\nu = 1554$ cm.$^{-1}$, $\nu = 2335$ cm.$^{-1}$, and $\nu = 4149$ cm.$^{-1}$, also suggest that the nuclei of these homopolar molecules even in the liquid state execute vibrations under impressed radiation, though no bands in these regions have so far been observed. One may thus be led to imagine that nuclear vibrations occur along the direction of propagation of the radiation and are thus optically inactive so far as absorption is concerned. Dennison (*Astro. Jour.*, **62**, 1925) calculated the fundamental frequencies of the methane molecule from dynamic considerations, and out of the four fundamental frequencies, three have been identified in the absorption bands and it has been suggested that the fourth one at $\lambda = 6{\cdot}58$ μ is optically inactive. The presence of such an optically inactive vibration is also suggested from the work of Bennet and Meyer on the spectra of methyl halides (*Phys. Rev.*, **33**, 895 ; 1929). It will be worth while to study the Raman effect of this gas to ascertain from the modified lines the presence of this fundamental frequency suggested from dynamical considerations.

The Raman Effect for X-rays.

IN a letter in NATURE of April 27, p. 642, we reported some experiments on the fine structure of the normal scattered molybdenum $K\alpha$-radiation. From our photometer curves it is clearly shown that the normal scattered molybdenum radiation from graphite has exactly the same structure as the direct radiation from a molybdenum target or, in other words, that no Raman effect exists. An analogous result was obtained by W. Ehrenberg (*Zeit. f. Physik*, **53**, 234 ; 1929) ; whereas B. Davis and D. P. Mitchell (*Phys. Rev.*, **32**, 331 ; 1928) obtained on the contrary a much more complicated structure in the case of the normal scattered radiation.

In the meantime the experiments were continued by D. P. Mitchell (*Phys. Rev.*, **33**, 871 ; 1929), and analogous results to those obtained with graphite are reported when beryllium and aluminium were used as scattering substances. Though for the moment we cannot explain the difference between Mitchell's results and our own, we should like to direct attention to the following fact : In the case of beryllium Mitchell finds an 'anti-Stokes line' which should be scattered by an atom in the excited L-state. Now a simple calculation shows that even when working with an energy so large as 3 kw., and such short distances as was done by Mitchell, much less than one beryllium atom in 10^{15} can be in the excited L-state. Hence it follows that it is quite impossible to account for the order of magnitude of the intensity of the anti-Stokes line quoted by Mitchell.

Adaptation.[1]

By Prof. D. M. S. Watson, F.R.S.

THE only great generalisation which has so far come from zoological studies is that of evolution—the conception that the whole variety of animal life, and the system of inter-relationships which exists between animals and their environment, both living and non-living, have arisen by gradual change from simpler or, at any rate, different conditions.

Evolution itself is accepted by zoologists not because it has been observed to occur or is supported by logically coherent arguments, but because it does fit all the facts of taxonomy, of palæontology, and of geographical distribution, and because no alternative explanation is credible.

Whilst the fact of evolution is accepted by every biologist, the mode in which it has occurred and the mechanism by which it has been brought about are still disputable. The only two ' theories of evolution ' which have gained any general currency, those of Lamarck and of Darwin, rest on a most insecure basis ; the validity of the assumptions on which they rest has seldom been seriously examined, and they do not interest most of the younger zoologists. It is because I feel that recent advances in zoology have made possible a real investigation of these postulates that I am devoting my address to them.

Both Lamarck and Darwin based their theories on the assumption that every structure in an animal had a definite use in the animal's daily life or at some stage of its life history. They understood by adaptation a change in the structure, and by implication also in the habits of an animal, which rendered it better fitted to its " organic or inorganic conditions of life ". Thus, for Darwin at any rate, a general increase in the efficiency of an animal was an adaptation. But amongst his followers the term came to imply a definite structural change of a part or parts by which an animal became better suited to some special and characteristic mode of life. The adaptation of flowers to ensure fertilisation by definite species of insects is a characteristic case. Such definite adaptations can only be shown to exist by very long continued observation of the animal under its natural conditions of life. In the post-Darwinian literature the suggestion that such and such a structure could be used for some definite function is too often regarded as evidence that in fact it is actually so used. My colleagues amongst the palæontologists are, I am afraid, offenders in this way.

Even if it can be shown that the structure of an animal is such that it is specially fitted for the life which it in fact pursues, it does not necessarily follow that this structure has arisen as a definite adaptation to such habits. It is always conceivable, and often probable, that after the structure had arisen casually, the animal possessing it was driven to the appropriate mode of life.

The only cases in which we can be certain that adaptation in this true sense has occurred are those, unfortunately rare, in which we can trace in fossil material the history of a phylogenetic series, and at the same time establish that throughout the period of development of the adaptation its members lived under similar conditions.

It is not unusual for a student of fossils to discuss the habits of an extinct animal on the basis of a structural resemblance of its ' adaptive features ' to those of a living animal and then to pass on to make use of his conclusions as if they were facts in the discussion of an evolutionary history or of the mode of origin of a series of sediments.

In extreme cases such evidence may be absolutely reliable : no man faced with an ichthyosaur so perfectly preserved that the outlines of its fins are visible can possibly doubt that it is an aquatic animal, and such a conclusion based on structure is supported by the entire absence of ichthyosaurs in continental deposits of appropriate ages and their abundance in marine beds. But if extremes give good evidence, ordinary cases are always disputable. For example, there is, so far as I know, not the least evidence in the post-cranial skeleton that the hippopotamus is aquatic : its limbs show no swimming modification whatsoever, and the dorsal position of the eyes would be a small point on which to base assumptions.

Most palæontologists believe that the dentition of a mammal, and by inference also that of a reptile or fish, is highly adaptive, that its character will be closely correlated with the animal's food, and that from it the habits of an extinct animal can be inferred with safety.

Here again the extreme cases are justified ; the flesh-eating teeth of a cat and the grinding battery of the horse are clearly related to diet. Crushing dentitions, with the modification of skull and jaw shape and of musculature which go with them, seem equally characteristic. I had always believed that the horny plates and the jaws of the platypus were adapted to hard food, and that that animal possessed them, whilst the closely allied *Echidna* was toothless, because it was aquatic and lived in rivers which might be expected to have a rich molluscan fauna that could serve as food. But the half-dozen specimens the stomachs of which I have opened contained no molluscs whatsoever, and seem to have fed on insect larvæ, the ordinary soft bottom fauna of a stream. I do not know whether this is an accidental occurrence, dependent on a special abundance of insects in the Fish River in late spring, or whether it really represents the normal food. Nothing but continued observations made throughout the year can justify any statements about this case.

In the face of this uncertainty, can we make use of the character of the dentition of fossil vertebrates for the determination of the nature of their food, and thus by building up phylogenetic series investigate the gradual development both of habit and their adaptation ? One without the other is valueless. The classical case of the horse is, of course,

[1] From the presidential address to Section D (Zoology) of the British Association, delivered at Johannesburg on Aug. 2.

familiar to everyone. From the time of Huxley the story of the gradual increase in depth of crown of the molar teeth and in the complexity of the pattern formed by the worn edge of the enamel which coats the cusps of the molars has been held to show a steady improvement in mechanism which enabled the Equidæ to take advantage of a wide extension of grass land which was assumed to have occurred in Miocene times.

This assumption in its ordinary form, however, rests on the basis of an inadequate analysis of all the factors involved. The modern horses are bigger than those of the Eocene: an ordinary hackney weighs about fifty times as much as *Eohippus venticolus*. Thus, the modern horse will wear away in a day fifty times as much tooth as its ancestor; but the surface area of its cheek teeth is only about fifteen times as great, so that without a deepening of the tooth crown by three and a third times it would have a shorter life. Actually the crown is deepened about thirteen times, so that its potential longevity is increased to about four times that of *Eohippus* on the assumption that the abrasive qualities of the food of the two animals have not changed. Dr. Matthew has produced evidence to show that in *Merychippus*, the Miocene genus of horse, tooth change took place at a younger age than it does in modern horses; the implication being that the potential longevity was less than it now is.

Thus the fact that *Equus* has proportionately some four times as much tooth as *Eohippus* may mean no more than that it lives longer, and its marvellous dentition may not be adaptive in the sense that it is specially modified for the trituration of a new type of food. It may represent no more than a reaction to the requirements of a large animal. I believe that most adaptations the history of which can be traced in fossil material are of a similar kind.

Whether a change which enables a mammal to become larger and to have a greater potential longevity is an adaptation may be disputed. Certainly it is very different from the usual conception of a structural change fitting an animal for a definite type of life in particular circumstances.

There are, however, a few cases where we are, I think, on firmer ground. The slow and steady improvements in limb structure which go on in the mammal-like reptiles from Lower Permian to Lower Triassic times take place in animals which do not exhibit a steady increase in size, which indeed cover nearly the same range of sizes at the beginning and end of the story.

In the earliest of these animals the upper arm projected at right angles to the body, and the forearm lay at right angles to it, nearly parallel to the ground. The track was very wide, the stride absurdly short, and only one foot could be moved at a time, whilst some of the muscles were devoted entirely to the support of the weight of the body, leaving the whole propulsive force to be supplied by the remainder, or rather by such of them as were not concerned with returning the limb to the position it occupied at the beginning of the stride. From these slow and clumsy ancestors we may trace the gradual acquirement of the structure found in *Cynognathus* or in a mammal; where the arm moves nearly parallel to the principal plane of the animal, the stride is greatly lengthened and every muscle contributes both to the support of the body and to its propulsion. Here we have a case where we can observe an improvement of an animal mechanism which definitely enabled an animal to move faster than its ancestor.

Such general improvements in the mechanism of an animal's body, which are the only adaptations which can be proved to have occurred, differ so greatly in scale and in their general nature from that detailed fitting of an animal to some particular niche in its environment which Darwin believed to occur, that it is important to investigate whether there is any general occurrence of such special relationship of structure and habit, and whether if it occurs it is rightly to be regarded as of adaptive origin. It is, I believe, in the first part of such investigation that a good deal of the future value of physiological work in zoology lies.

The physiological work which is at present being conducted by zoologists falls under two main heads. It may be concerned with the explanation in physico-chemical terms of definite life processes, such as fertilisation or cleavage, the activities of cilia or the nature of muscular activity. Such work is of value to zoology because it increases our knowledge of the cell and all its parts and of the things which may control its activities. It will become essential for an understanding of the factors which underlie morphogenesis, that is, of those factors some of which are carried as material bodies in the chromosomes.

The other type of physiological work is that which, like the classical 'experimental physiology' of the medical school, is devoted to an attempt to understand the functioning of the different systems of organs and ultimately of the whole body of an animal. I believe that such studies hold out the greatest promise of results of any in zoology. We do not know even as a first approximate the mode of working of the body of any one member of the majority of the phyla of the animal kingdom. Until such is known, in at least a few individual species of each phylum, we shall not be in a position to understand the possibilities of adaptation which each fundamental type of morphology holds out and the real significance of the fitting of an animal to its environment.

The ecological relationships of animals to their environments present many aspects which are now capable of investigation by simple physiological experiment, and South Africa seems to me the country of all others which could provide the subjects for such an investigation.

Physiological work of the kind which I suggest, although it will show to what extent there are variations between races and species of animals which fit them specially for life under definite physical environments, will not in general elucidate those morphological differences which alone are recognisable in a museum, and have commonly been assumed to be of an adaptive nature. That these structural

differences are adaptive even in the sense that, no matter in what circumstances they arose, they do now in fact fit each form especially to its circumstances, is for the most part pure assumption. I do not know a single case in which it has been shown that the differences which separate two races of a mammalian species from one another have the slightest adaptive significance.

There is no branch of zoology in which assumption has played a greater, or evidence a less, part than in the study of such presumed adaptations. The implication which lies behind any statement that such and such a structure is an adaptation is that under the existing environmental conditions an individual possessing it has a greater chance of survival than one which has not.

The extraordinary lack of evidence to show that the incidence of death under natural conditions is controlled by small differences of the kind which separate species from one another or, what is the same thing from an observational point of view, by physiological differences correlated with such structural features, renders it difficult to appeal to natural selection as the main or indeed an important factor in bringing about the evolutionary changes which we know to have occurred. It may be important, it may indeed be the principle which overrides all others ; but at present its real existence as a phenomenon rests on an extremely slender basis.

The extreme difficulty of obtaining the necessary data for any quantitative estimation of the efficiency of natural selection makes it seem probable that this theory will be re-established, if it be so, by the collapse of alternative explanations which are more easily attacked by observation and experiment. If so, it will present a parallel to the theory of evolution itself, a theory universally accepted not because it can be proved by logically coherent evidence to be true but because the only alternative, special creation, is clearly incredible.

The alternative explanations which are put forward of the existence of the differences which separate species from species or one geographical race from another are in essence three : either the difference is regarded as adaptive and its initiation and perfectioning are attributed to a reaction of the animal which alters its structure in a favourable manner followed by an inheritance of the character so acquired ; or, secondly, it is regarded as non-adaptive, or only accidentally of value, and held to have arisen by a change induced in the course of an individual development by the direct effect of some one or more environmental features, such change not necessarily being heritable in all cases. The third explanation is that the difference between one form and the other has arisen casually, isolation having enforced an inbreeding which led to the distribution of genes in different proportions in the two stocks.

The first alternative explanation suffers from the defect that the characters in question have not in general been shown to be adaptive, and that an inheritance of an acquired character of the kind required has not been shown to occur.

The second explanation, the direct influence of the environment, has the immense advantage that it is open to investigation by experimental methods, and suggests many attractive lines of work. Here again experiments have been few. The most successful is that on the induction of melanism in moths by Heslop Harrison and Garrett. By feeding caterpillars on food impregnated by salts of manganese or lead, these authors, in three independent series of experiments, obtained melanic individuals of a character which did not occur in the much larger numbers of controls fed on untreated food, nor under natural conditions in the district of origin of the parent individuals.

Harrison and Garrett attribute the melanism which appeared under these conditions to the direct effect of the metallic salts, either on the soma or, as is perhaps more probable, on the germ cells. They showed by a very adequate series of breeding experiments that the melanism which arose in this way is inherited as a simple Mendelian recessive.

It is obvious that such a direct environment effect, when taken in association with the completely established fact of the common occurrence of parallel or identical mutations in allied animals, provides a complete formal explanation of such facts as that the coat-colour of a race of a species of rodent from an arid region will in general be lighter in colour than that of a race from a more humid and therefore more thickly vegetated area. It is clear that such an explanation does not require that the coat-colour has any adaptive significance whatsoever : it is in complete contrast with the equally formally complete explanation by natural selection. But it has the advantage that it can be submitted to experimental confirmation.

The neo-Darwinian would explain this occurrence by assuming that the dark-coloured forms were less visible against the moist and therefore darker soil of the humid locality than lighter animals would be, and would thus escape the attacks of carnivores for a longer period. The light forms would escape notice under the bright illumination and glitter of an arid and especially a desert country. Such a view assumes without question that the colour of the two groups is heritable, though it makes no demands for any particular type of heredity.

The only experiments which have been made with geographical races of mammals are those which Sumner has carried on over many years. Sumner began his work by collecting considerable numbers of individuals of a certain species of the deer-footed mouse *Peromyscus* from localities in California which present extreme variations in rainfall and temperature. He showed that the mice from each locality varied, and that the distribution of the variates for each character formed a unimodal curve. He investigated by statistical methods the correlation between pairs of the characters with which he worked, showing that for many of them the correlation was small. He showed that the curves for different subspecies might overlap, so that no one individual could fairly represent its race.

Sumner also attempted to investigate the possibility of such environmental influences by direct experiment. He transplanted a small colony of

mice into a very different environment, enclosing them in a small netted area and leaving them to breed. The offspring which appeared during the course of the experiment showed no tendency to approach the local races in their characters.

It may be accepted as a working hypothesis that the variable characters which separate one geographical race from another are produced under the influence of a number of genes, all independent, and all producing similar effects. As Prof. Karl Pearson pointed out in 1904, the effect of such multiple factors will be to produce an apparent blending inheritance ; a view now very generally accepted. It follows that, in certain cases at any rate, if a small group of individuals phenotypically similar, though genotypically different, differing from the norm of a population, be isolated and left to breed freely, they will, when considered as a population, tend to vary still more from the original mode in the population from which they sprang and that they will do so in the direction in which the original isolated group differed. Prof. Pearson has reached the same conclusion from his own very different point of view and has evidence that the expected result does actually occur.

If, then, we can conceive of circumstances which will bring about such isolation in such a way that the individuals so separated are determined by an environmental condition, we shall have an explanation of the divergence of local races which will account for the appearance in them of individuals which lie outside the range of variation actually observed in the small samples of the parent races which have been investigated.

There remains one type of adaptation which is perhaps of greater importance than those which we have been considering. Perhaps the most striking of all the phenomena of life is the power which all animals and plants possess of so regulating their functioning, and when necessary their morphology, that their life is continued in equilibrium with the conditions under which they find themselves.

How far such physiological adaptations are of the same nature as those internal morphological adaptations which alter the relative sizes of parts in ways determined by geometrical considerations of squares and cubes, and produce analogous modifications in other structural features, there is no evidence. What is certain, however, is that these, which are the fundamental things in evolution, lie open to experiment.

Thus the present position of zoology is unsatisfactory. We know as surely as we ever shall that evolution has occurred ; but we do not know how this evolution has been brought about. The data which we have accumulated are inadequate, not in quantity but in their character, to allow us to determine which, if any, of the proposed explanations is a *vera causa*. But it appears that the experimental method rightly used will in the end give us, if not the solution of our problem, at least the power of analysing it and isolating the various factors which enter into it.

The Relation of Organic Chemistry to Biology.[1]

By Prof. GEORGE BARGER, F.R.S.

SINCE, in the last resort, we are dependent on naturally occurring materials, which scarcely ever occur in a state of purity, it follows that the early chemists were even more concerned with separating one substance from another than many of us are to-day. Progress was at first limited to mineral substances capable of withstanding powerful reagents and a high temperature ; much of the old chemistry is concerned with the heavy metals. The substances formed in such large numbers by living beings are much less stable, and their isolation demands a special technique. It is significant that, in spite of their knowledge of the smelting of ores, of the manufacture of glass, and of many other arts, the ancients failed to distil alcohol. Later, the chemical investigation of organic material was apt to consist in destructive distillation, naturally adding little to knowledge. Only the more volatile and stable substances could be isolated in this fashion.

An important systematic advance was made by K. W. Scheele (1742–1786), whose contributions to organic chemistry are almost as important as his discovery of oxygen. Scheele was a pharmacist, and most of the early chemists were trained as such, or as physicians, from the iatro-chemical period onwards. This old connexion between chemistry and medicine was, however, scarcely a biological one. Joseph Black's work on fixed air and the mild alkalis indeed originated in medicine, from his M.D. dissertation, "De humore acido a cibis orto et magnesia alba", but the subsequent developments of Black's work were not biological in character. Again, although Berzelius was trained as a physician, his work had little connexion with biology.

The use of vegetable drugs, however, led pharmacists to examine the constituents of plants, and thus the foundations of descriptive biochemistry were laid. Scheele investigated a number of organic acids in the wet way. He obtained tartaric acid in 1769, and later benzoic acid by boiling gum benzoin with lime. He first prepared lactic acid (1780) from sour milk, and mucic acid by oxidation of milk sugar. When, soon afterwards, mucic acid was also obtained from gum tragacanth, it became evident that one and the same substance may be derived from both animal and vegetable sources. Oxalic acid was obtained from the acid potassium salt in *Oxalis acetosella*, and shown to be identical with an oxidation product of cane sugar. Scheele also obtained citric, malic, and even gallic acid by crystallisation from solution. Of more general biological interest is his discovery of uric acid, of glycerol, and of hydrocyanic acid ; the last (acidum berolinense) by heating potassium ferrocyanide with dilute sulphuric acid.

[1] From the presidential address to Section B (Chemistry) of the British Association, delivered at Cape Town on July 23.

Scheele's discovery that esterification is greatly furthered by the presence of mineral acids later became important in connexion with catalysis, but theoretical speculations were foreign to his nature, and he was not greatly concerned with the essential character of acids. Such questions appealed more strongly to Lavoisier, who improved the nomenclature of organic acids and also investigated alcoholic fermentation, a biochemical process which early engaged the attention of chemists.

A knowledge of structure gave a great impetus to organic synthesis, not only in the laboratory for theoretical purposes, but also in the factory for practical uses; the manufacture of dyes, of synthetic drugs, of explosives became an important industry. The number of known carbon compounds grew at an enormous rate. Instead of being the chemistry of organised beings, organic chemistry became the chemistry of carbon compounds. Until the present century the proportion of chemists who, like Scheele, were interested in natural products steadily declined, and biology became of little interest to chemists as a whole, but physiologists have more and more realised the importance of chemistry for their subject and the intermediate subject of biochemistry has rapidly developed.

The systematic study of natural products, inaugurated by Scheele, was at first continued most successfully in France by Fourcroy, Vauquelin, and their pupils. Braconnet examined plants and discovered substances such as salicin and ellagic acid, of no particular importance to physiology, but also obtained glucose from cellulose (linen) and 'sucre de gélatine' or glycine from glue, thus making two fundamental observations in biochemistry. Kirchhoff, a German pharmacist, working at St. Petersburg, had already shown in 1811 that glucose is formed from starch, and investigated the process of malting. In 1833, Payen and Persoz discovered the first enzyme, diastase, and in 1827 a medical practitioner of London, W. Prout, better known to chemists in another connexion, could say in a paper "On the ultimate composition of simple alimentary substances" that they might be arranged in three classes, "the saccharine, the oily, and the albuminous".

By analysis Gay-Lussac was able to establish the fundamental equation for the fermentation of glucose into alcohol and carbon dioxide, and the first systematic advance in biochemistry, also due to analysis, was Chevreul's great work on the fats. In 1824, Wöhler obtained oxalic acid from cyanogen, the first synthesis of a vital product, if we except Scheele's production of cyanides from carbon, potassium carbonate, and ammonium chloride. Four years later, in 1828, Wöhler's synthesis of urea attracted universal attention, and since then much labour has been expended on the synthesis of vital products as an ultimate proof of their structure.

Wöhler had apparently no connexion with medicine or pharmacy, but Liebig was a pharmaceutical apprentice for one year, Frankland a druggist's assistant, Dumas, Schorlemmer, and even Wilhelmy, who investigated the kinetics of sugar hydrolysis, were pharmacists. Gmelin, Mitscherlich, Wurtz, and Cannizzaro studied medicine; even in the present century medically qualified professors of general chemistry survived (Crum Brown, Emerson Reynolds). The pharmacists soon found a special field of research in alkaloids, essential oils, and other products of the materia medica. Within a few years of the recognition of the first organic base, morphine, by the German pharmacist Sertürner, a dozen alkaloids had been discovered, mostly in France, by Pelletier and Caventou, professors at the École de Pharmacie. It is presumably due to this institution, and to the high standard of pharmaceutical education in France, that the scientific output of French pharmacists has been so long maintained. For recent times we may refer to Bourquelot, professor at the École de Pharmacie, and to Charles and Georges Tanret, father and son, both practical pharmacists, who not only made important contributions to our knowledge of drugs but also to that of sugars. In Germany contributions of pharmacists to organic chemistry were of less importance, compared with the great developments in university research inaugurated by Liebig and fostered by the German States.

In Britain the State did very little for the universities and nothing for pharmaceutical teaching; although British pharmacists have the exclusive legal right to call themselves 'chemists', the State has not helped them to justify the title. At first the British themselves contributed little to organic chemistry; of the pioneers Faraday, Frankland, Perkin, and Williamson, only two were teachers. The sojourn of Hofmann in London, from 1845 to 1865, from the age of twenty-seven to that of forty-seven, was of the greatest influence on the development of organic chemistry in England, but it did not lead to biological applications. Particularly through the inauguration of the dye industry, by Hofmann's pupil, Perkin, and Mansfield, attention was directed to practical problems.

As a result of Emil Fischer's work, the new science of biochemistry was firmly established in the beginning of the present century. It should not be supposed that organic chemical theory is wholly unconnected with biology. Two examples out of many will show the contrary. When a protein is 'racemised' so far as possible, by Kossel's method, by leaving it for some weeks at 37° in half-normal alkali, it is found that certain amino-acids retain their optical activity, and these Dakin has assumed to be the ones with free carboxyl groups, situated at the ends of chains. The others undergo racemisation probably because in their case tautomerism is possible:

$$\begin{array}{l}\text{—CO . NH . CR′H . CO . NH . CR″H . COOH}\\ \qquad\qquad\qquad\qquad\qquad\qquad\uparrow\downarrow\\ \text{—CO . NH . CR′ : COH . NH . CR″H . COOH.}\end{array}$$

On subsequent acid hydrolysis the amino-acid NH_2 . CR′H . COOH would be racemic, but NH_2 . CR″H . COOH optically active. Dakin's views were first applied by Dudley and Woodman to show a structural difference between the caseinogens from cow's milk and sheep's milk, which had been considered by some to be identical.

Elementary analysis shows no difference, and individual amino-acids are obtained in the same amounts after hydrolysis. After racemisation, however, Dudley and Woodman found the tyrosine from cow's caseinogen to be wholly inactive, that from the sheep fully active. In the former animal the tyrosine is probably inside the molecule, in the latter it is on the periphery. We are thus able to discover differences in the intimate pattern of the molecule. Dakin and Dale connected these differences with antigenic specificity.

Crystallised albumins from the whites of hens' and ducks' eggs are very similar and seem to be composed of the same units in equal amounts, but Dakin found that three amino-acids, leucine, aspartic acid, and histidine, behave differently to alkali in the two molecules, and appear to occupy different places. Hen's albumin has some aspartic acid but no leucine or histidine on the periphery; duck's albumin, on the other hand, has no aspartic acid, but some leucine and histidine on the outside of the molecule. By the very sensitive anaphylactic reaction of the isolated guinea-pig's uterus, Dale showed that the two proteins are specifically different as antigens. Differences in arrangement, even of the same amino-acids, help to differentiate the proteins of various species. It is on the diversity of the proteins that the difference of species is based.

Another recent example of the application of organic chemical theory to biology is due to Stedman. Having traced the miotic action of physostigmine to a urethane grouping, he synthesised a number of urethanes of simple dimethylaminophenols, for example, $R.NH.CO.O.C_2H_4.N(CH_3)_2$. The physiological activities of the tertiary bases is generally in the order ortho and para > meta, but on conversion into quarternary salts the ortho and para become less active, the meta more so, and the order is meta > ortho or para. This recalls the reactivities of disubstituted benzene derivatives, which have of late been studied in connexion with the polarity theory.

Whilst organic chemists are often eager to investigate the constitution of animal and vegetable substances, they are less ready to undertake the preliminaries of purification and isolation, and are therefore less apt to discover new ones. By esterification and by the use of a high vacuum, Emil Fischer made the monoamino-acids amenable to fractional distillation, a standard operation of organic chemistry. He discovered several new members of the group. But most substances of physiological interest require a special technique, on the development of which the biochemist may spend much labour. Thus Kossel showed how to separate the purine and pyrimidine bases of the cell nucleus, and the important diamino-acids histidine, arginine, and lysine. Hopkins, by his special reagent, was able to isolate tryptophane, the parent substance of indigo, long after indigo itself was being manufactured synthetically. Dakin found that monoamino-acids can be extracted from aqueous solution by butyl alcohol, and using this new technique and Foreman's method of separating aspartic and glutamic acids by their calcium salts, Dakin discovered hydroxyglutamic acid, an entirely unsuspected unit of protein.

A knowledge of the structure of amino-acids may throw light on how other nitrogenous constituents arise, particularly in plants. As an example the most recently discovered amino-acid may be quoted. The American bacteriologist Mueller found in casein and other proteins a new constituent containing sulphur, quite different from the well-known cystine. Dr. Coyne and I have recently established its constitution by synthesis. It turns out to be γ-methylthiol-α-amino-*n*-butyric acid, $CH_3.S.CH_2.CH(NH_2)COOH$, and we named it methionine. The methylthiol grouping at once indicates that it is the source of methylmercaptan, the occurrence of which in putrefaction was known although not hitherto intelligible. Methionine is evidently also the parent substance of cheirolin, occurring in the seeds of the wallflower and of other Cruciferæ. Schneider had long ago established for this substance the remarkable constitution $CH_3.SO_2.CH_2.CH_2.CH_2.N.CS$. We now see at once that cheirolin is the thiocarbimide of oxidised and decarboxylated methionine. Similarly Perkin and Robinson connected the chemistry of harmine and harmaline with tryptophane when they showed that the mysterious base $C_{12}H_{10}N_2$, which Hopkins and Cole obtained by oxidising tryptophane $C_{11}H_{12}O_2N_2$, with ferric chloride, is identical with harman. This observation not only settled the constitution of the alkaloids in question, but also explained the fitful yield of the oxidation product of tryptophane, which, after decarboxylation, had condensed with acetaldehyde.

Soon afterwards, Späth showed that harman itself occurs in Nature, as the alkaloid aribine which had been given the erroneous formula $C_{23}H_{20}N_4$. It is becoming increasingly evident that many alkaloids arise by condensation of amino-acid residues. Mezcaline and other alkaloids of Cactaceæ are closely connected with phenylalanine and tyrosine, as Späth has shown, and the mode of origin of *iso*quinoline alkaloids from aromatic amino-acids has also become clear. Harmine, harmaline, physostigmine, and rutæcarpine are all derived from tryptophane, and it looks as if the same is true of other alkaloids the constitution of which, like that of strychnine and of brucine, remains obscure.

The isolation of some natural substances, of great physiological interest, is beset with difficulties because they are present in minute amount and have not the convenient solubility relations which facilitate the separation of the alkaloids. This applies to the hormones present in animal tissues. Here the American slaughter-houses provide valuable facilities, and it is significant that adrenaline, thyroxine, and insulin were first crystallised in America, although the constitution of the two former hormones was later established in Europe where also their synthesis was effected, that of thyroxine only a few years ago, through the brilliant work of Harington.

The difficulty of isolating vitamins is still more formidable; in the case of the antineuritic vitamin B, which is almost certainly a fairly simple sub-

stance, susceptible to attack by the methods of organic chemistry, much progress towards isolation has been achieved by selective adsorption and elution, the methods employed by Willstätter for enzymes. The discovery by Rosenheim and Windaus that vitamin D is formed by the irradiation of ergosterol has suddenly brought into prominence a substance which before was but a curiosity, chiefly known through the work of the French pharmacist, Tanret. At the same time the interest of biochemists in photochemistry has been stimulated, as well as in the extensive work of Windaus on the structure of cholesterol, which the latter had already shown to be connected with the bile acids, largely investigated by Wieland.

The sudden emergence of ergosterol into prominence does not stand alone; another of Tanret's ergot substances, ergothioneine, at first also an isolated curiosity, has acquired more general significance because it has been found in mammalian red corpuscles; it is likely that this will lead ultimately to the discovery in proteins of yet another sulphur-containing amino-acid, possibly a thiolhistidine. Altogether, ergot has yielded more substances of general biological interest than any other single plant.

The above examples of the relation between biological and organic chemical work relate to that division of biochemistry which may be termed descriptive. A knowledge of structure is also necessary in dynamic biochemistry, the study of the transformations which substances undergo in the living organism. The recognition of the fats as esters, and their behaviour to fat-splitting enzymes, the transformation of starch into sugar under the influence of diastase, the end-products of alcoholic fermentation; all these were early discoveries in dynamic biochemistry.

Just as the organic chemist may wish to know the mechanism of a reaction, for example of the Skraup synthesis of quinoline, so the biochemist wishes to know the intermediate steps in the transformation of, say, glucose into alcohol. The detection of these stages of metabolism is a matter of considerable difficulty, since under normal conditions the intermediate substances generally disappear as rapidly as they are formed. They have to be trapped by suitable means, as did Neuberg with acetaldehyde in alcoholic fermentation, or the metabolic process may sometimes be cut short, by using an isolated organ, such as the surviving liver, or the precursor of the intermediate substance may be administered in large excess.

Very little has been learned in this respect from the higher plants. The very process of photosynthesis is still beset with obscurity in spite of a plausible hypothesis; we know next to nothing about transformation of carbohydrate into fats, and vice versa, and in particular we are ignorant of the stages by which amino-acids are formed in plants from nitrates and carbohydrates; we simply do not know how the proteins of living beings originate. Nor have the higher plants given us much information of the way in which their fats, carbohydrates, and proteins are ultimately broken down.

Our knowledge of catabolism is principally derived from the animal world. It is found that the breakdown does not always occur in the manner in which the organic chemist would expect. Thus an organic chemist presented with the problem of transforming stearic acid into palmitic might brominate in the alpha position, and break down the corresponding α-hydroxy acid; or he might do a Hofmann degradation on the amide. In either case he would get an acid with 17 carbon atoms, and have to repeat the degradation in order to obtain palmitic acid. Knoop has shown, however, that in the animal organism the β-carbon atom is attacked so that the chain is shortened by two carbon atoms at a time, an acid with 18 carbon atoms being converted successively into one with 16, 14, 12, etc. In accordance with this scheme the principal fatty acids in Nature are those with an even number of carbon atoms. Knoop established this by feeding ω-phenyl fatty acids; those with an even number of methylene groups in the side chain were converted into benzoic acid and appeared in the urine as hippuric, those with an odd number of methylene groups yielded phenylacetic acid and were excreted as phenaceturic acid. Instead of using a resistant phenyl group and the whole animal, fatty acids themselves and the isolated liver may be used to establish the same result.

The degradation of amino-acids in the body also proceeds contrary to the expectations of the organic chemist. If he were asked to bring about the degradation by gentle stages he would doubtless first convert the α-amino into the α-hydroxy acid. The organism forms the α-keto acid, however, as shown by Neubauer and by Knoop. This biochemical result suggested to Knoop an interesting and unlooked-for synthesis of amino-acids *in vitro*, by reversing the normal breakdown. He shook solutions of α-keto acids, containing also ammonia and platinum black, in a hydrogen atmosphere, when the corresponding amino-acid resulted by the reduction of the hypothetical imino-compound. The transformation of tryptophane into kynurenic acid may be quoted as a particular problem of metabolism to which a good deal of organic chemistry has been applied.

The first stage in the degradation of fatty acids and of amino-acids seems pretty well established, and analogies *in vitro* have been found. Other problems are more obscure. Why is the benzene nucleus in phenylalanine oxidised, but not that in benzoic acid? What is the mechanism in the former case? Why is *p*-hydroxyphenylpyruvic acid easily oxidised and the corresponding lactic acid not? Why is *d*-phenylglycine easily oxidised and *l*-phenylglycine excreted almost unchanged? Altogether, the processes by which organic substances are burnt to carbon dioxide and water, by atmospheric molecular oxygen, at a low temperature, are still very puzzling, although Dakin, Hopkins, Knoop, Warburg, Wieland, and others have done much towards their elucidation. In the study of the chemical processes, as in that of the chemical constituents of living organisms, there is much scope for the application of organic chemistry,

and in addition, physical chemistry requires to be utilised.

Probably the most extensive attempt to use chemical constituents for botanical classification has been made by R. T. Baker and H. G. Smith, in the case of the Australian genus *Eucalyptus* with about two hundred species : the essential oils from well over half of these have been examined. Baker and Smith trace a relation between the venation of the mature leaves and the composition of their essential oil. The genus is thus divided into fairly well-marked groups, and it is possible to suggest the probable constituents of the oil of a given species by examining the venation of the leaves, and, conversely, by chemical investigation of the oil to gain a clue to the species. Maiden, the botanical expert on *Eucalyptus*, did not always agree with the classification of the chemists, but upon occasion he discovered morphological differences after a delimitation of species had been proposed on chemical grounds.

The main biological interest of alkaloids is not botanical in their distribution, but pharmacological in their action. This leads to a mention of the great developments in synthetic drugs, due to organic chemistry. In particular there is great scope for the organic chemist in chemotherapy, the combating of general infections of the host by synthetic drugs. The production of salvarsan, which has made such a great change to the treatment of syphilis and other protozoal diseases, and the subsequent introduction of germanin (or Baye 205) in the treatment of sleeping sickness, indicat great possibilities of applying organic chemistr to this particular department of medicine, an constitute a link between workers in very differen fields.

I have directed attention to the many points o contact between organic chemistry and biology in the past and present, and if finally I am permitte to draw a conclusion it would be an educational one I hold it to be desirable that biologists should hav at least an elementary knowledge of organi chemistry, in spite of the difficulties imposed b ever-increasing specialisation in science. Thes difficulties are particularly felt in apportioning th time available for medical education among th many subjects of a crowded curriculum, and ma to some extent be met by a careful consideratio of what is really useful.

The chemical training of the physician (and o the biologist) should not be identical with th preliminary training of the professional chemist although it still is so in many universities. I order to save time, much elementary chemistry particularly inorganic, must be abandoned, thu making room for those aspects of the subject whic have biological applications. This differentiatio between the chemical needs of various groups o students requires special courses, and teachers wh have a sympathetic understanding of the peculia needs of their students, medical and biological.

Obituary.

Prof. Charles Moureu.

NOT only the French but also chemists generally suffer a specially severe loss by the death of Charles Moureu, professor of organic chemistry in the Collége de France, the second to succeed Berthelot. In France, the leader in his subject, he was not merely a chemist of great achievement and high repute but also a man of outstanding personal character and social distinction. During the War he rendered inestimable service to his country by organising and directing the work—defensive and offensive—of the French chemists ; in this connexion he was brought into close contact with our English workers. Since then he has been a familiar figure in England.

At the close of the War, Moureu entered upon a vigorous campaign in which he made clear to politicians and the public the importance of chemistry in the modern State and the great need of improving the status and financial position of the French scientific schools. His efforts to this end were in large measure successful. His success was in no slight degree due to the eloquence with which he stated his case in his book " La Chimie et la Guerre ". Known throughout the world of chemistry, a shrewd man of affairs, a polished diplomat, in fact, Moureu was particularly endeared to the chemists of other nationalities, who met him during recent years at various international conferences, by his engaging manner and the obvious sincerity and breadth of his outlook. The thesis developed in his book is that stated by hi countryman Duclaux, which he quotes : " L chimie est au fond de tout et rien ne lui échappe " He expressed what to him was a profound truth when he said : " Le Français le plus illettré a l sentiment, net ou confus, que sa patrie est grand et belle entre toutes. Fier, sans arrogance, d'êtr Français, il est profondement patriote." Patrioti to the core, at the same time he was so scientific ally minded, so sane in his judgments, that he wa not only willing but also able to deal with inter national problems broadly and dispassionately. H was the first president of the International Unio of Pure and Applied Chemistry and contribute greatly to the foundation of the Union. At th conference at the Hague last summer, he rendere most important service in the very difficult dis cussion on the constitution of the Union whic occupied the meeting.

Moureu was a son of the mountains, a native o the Basque region. He was born on April 19, 186 at Moureux, a village in the Bearnese country, i which his family had lived during centuries ; h died at Biarritz on June 13. An eloquent funera discourse was delivered there, by his colleague an friend, Prof. Camille Matignon, on June 17 ; h was buried the following day at Oberon, in th Basses Pyrénées. The youngest of a large family his father having died while he was an infant, h was cared for by an elder brother, Félix Moureu who lavished upon him the affection of a fathe

n affection which, throughout his life, he fully eciprocated. Félix Moureu died only last year, at ie age of seventy-eight. He was a pharmacist f distinction in Biarritz, ten years Mayor of the own; he did much to develop its attractions. harles Moureu's early training was in his brother's harmacy at Biarritz. In Paris, he quickly passed rough the courses in pharmacy and those at the orbonne. He qualified as pharmacist, in the first ass, in 1891. After serving, during several years, s chief assistant, he was admitted to the Faculty f Pharmacy in 1899 and became professor of harmaceutical chemistry in 1907. Ten years later e succeeded Jüngfleisch, Berthelot's successor in ie chair of chemistry at the Collége de France. Ie also became Director of the Verdun Agricultural esearch Station, founded by Berthelot. He was lected into the Academy of Medicine in 1907 and nto the Academy of Sciences in 1911. During iore than thirty years he has been a prolific worker.

Moureu began by studying various vegetable ssences, eugenol, etc. He also worked on alka- oids, determining the constitution of sparteine. ollowing the Berthelot tradition, he devoted him- elf to synthetic studies in the acetylene series. His iost noteworthy discovery is that of the *red ydrocarbon*, rubrene, which is remarkable on ccount of the way in which it simulates the ehaviour of hæmoglobin towards oxygen, absorb- ng the gas with avidity, *when irradiated*, forming a olourless peroxide from which the oxygen may be emoved by exposure in a vacuum. If heated, at emperatures below 140°, this gives off oxygen lone, to within 80 per cent of the theoretical mount. Even at ordinary temperatures, if ex- osed to light but not in the dark, the peroxide issociates reversibly, the dissociation pressure at 6° being of the order of 0·5 cm. of mercury. ight is emitted during the deoxidation. If the ydrocarbon be subjected to oxygen in admixture ith either benzaldehyde or propionic aldehyde nly the rubrene absorbs the gas; its oxidation s retarded by quinol and other anti-oxidants; it is ot oxidised at all in the presence of carbonic oxide. Ioureu has suggested, in view of the behaviour of ubrene towards oxygen, that in oxyhæmoglobin he oxygen may well be in organic connexion with he molecule, not through the iron.

From 1906 onwards, Moureu devoted himself to he study of the rare gases present in French ineral waters, oil springs, etc., even extending his esearches in this field to Madagascar, where he ade a careful survey of the chemical resources of he island. For this last service he was promoted o the rank of Grand Officer of the Legion of Ionour. A summary of his work on the rare gases as presented to our Chemical Society, of which e was an honorary member, in a lecture which he elivered on June 14, 1923. Fifty-seven springs n all were studied. The results are very remark- ble. The amount of helium present varied greatly, eaching 5·92 per cent in the gas collected at Iaizieres, Côte d'Or. The other gases, krypton, rgon, neon and xenon, however, were present in ractically the same proportion, whatever the source. In 1913 he initiated an Institute of Hydrology and Climatology for the study of mineral waters and problems of climate in France and its colonies.

Being familiar with acrolein from his early studies, during the War Moureu sought to utilise this aldehyde as a tear excitant. The difficulty was to preserve it unchanged, as it soon set to a solid. Having traced the polymerisation to the action of acid formed by atmospheric oxidation, he set to work to discover means of preventing the change. He soon found that a great variety of substances could be used as anti-oxidants: phenols, aldehydes, amines, even potassium iodide. From 1919 onwards, Dufraisse and he, assisted by various young workers, systematically explored the field thus opened up, with the result that we are now in possession of a mass of exact data of extreme value. The full importance of the work, in its bearing upon vital phenomena, is yet to be realised. It is already clear that, more often than not, when two oxidisable substances are together subjected to attack by oxygen gas, oxidation is apparently inhibited because both are simultaneously oxidised to oxides which interact reversibly. Obviously, if the living organism were not in some way protected against excessive oxidation, through the heat developed, the action would necessarily tend to take place at an increasing rate: there is little doubt that, through what may be termed the Moureu effect, a control is exercised preventing excessive action. Maybe the office of some advitants is of this order.

Moureu's work in general is characterised by a breadth and philosophical exactitude which renders it of special importance and value. In him we lose a true chemist of the old school—a man who worshipped at the shrine of severe laboratory practice, a cult to-day by no means overpopular even in France. Fortunately, the name survives in his son, already a young chemist of distinction.

Henry E. Armstrong.

Mr. H. C. Robinson.

Mr. Herbert Christopher Robinson, who was born in Liverpool on Nov. 4, 1874, died on May 30 last, after an illness which had lasted for nearly a year. Mr. Robinson belonged to one of the leading Liverpool families, whilst one of his uncles, Mr. William Fothergill Robinson, had been Vice-Chancellor of the Duchy of Lancaster.

Robinson was educated at Marlborough College, and on leaving school went to the Royal School of Mines, for which he had obtained a scholarship. In 1894, constant ill-health compelled him to give up his studies, and he then commenced his career as a zoologist at Davos, where he resided for a couple of years. Here his health considerably improved, and in 1896 he went to Queensland, where he made a large collection of birds in Cooktown and its vicinity, but was obliged to return home owing to chronic dysentery. On his return to England he was appointed an assistant in the Liverpool Museum, where between 1897 and 1900 he

assisted Dr. H. O. Forbes to publish catalogues of the bird collections in that Museum. In 1901 he accompanied Dr. N. Annandale, who was then Director of the Indian Zoological Survey, to the Malay Peninsula, on an expedition attached to the Skeat Expedition which had been organised by the Royal Society of Edinburgh and by the University of Liverpool. The results of this expedition appeared in several volumes between 1903 and 1907, that on birds being written by Mr. Ogilvy Grant in 1905—but the work, which was entitled "Fasciculi Malayenses", was unfortunately never completed.

In 1903 Mr. Robinson was appointed curator of the Federated Malay States Museums, and shortly afterwards, on the resignation of the Director, Mr. Wray, he was promoted to that appointment, which he held until his resignation in 1926. From this time forward Mr. Robinson—latterly often in conjunction with Mr. Boden Kloss—wrote from time to time many articles on the various branches of zoology, though principally on the Vertebrata. In addition to this, Mr. Robinson organised and directed both the Federated Malay States Bureau of Fisheries and also the Meteorological Service. For the last two years of his service Mr. Robinson was in charge of a section of the Malayan Pavilion at the Wembley Exhibition. Throughout his directorship of the Federated Malay States Museums, Mr. Robinson wrote principally in the *Journal* of those Museums, the *Journal* of the Asiatic Society, and, to a less extent, in the *Ibis*.

Mr. Robinson was not only a scientific ornithologist with a wide knowledge of the literature of birds, but was also himself a keen and indefatigable field naturalist with an intimate knowledge of the birds in a state of Nature, a fact which made his writings of interest as well as of value. Among the more important of his articles may be mentioned the various catalogues of the birds of Siam, different States of the Malay Peninsula and the larger islands, which appeared from time to time in the journals already mentioned, as well as in the *Journal* of the Natural History Society of Siam. His most important work, however, was the one on which he was engaged at the time of his death, which he was producing for the Government of the Malay States. It was intended that this work on the birds of that country should be divided into five parts: (1) Commoner Birds; (2) Birds of the Higher Hill Stations; (3) Sporting and Shore Birds; (4) Birds of the Low Country; and (5) Remaining Birds. Of these parts only the first two have appeared, though we understand that part 3 was also practically finished before Mr. Robinson's death. The two volumes in print prove the great loss that ornithology has sustained in the death of Mr. Robinson.

It can scarcely be said of Mr. Robinson that he was widely popular, for he was very reserved; at the same time, the better he was known the more he was liked. In manner most unassuming, he was yet always ready to assist his brother ornithologists to the utmost of his capacity, and to these his death means the loss of a great personal friend and a clever scientific worker.

WE regret to announce the following deaths:

Dr. Etienne Bieler, deputy-director of the Imperial Geophysical Experimental Survey, at Geraldton, West Australia, on July 25, aged thirty-four years.

Dr. W. G. Duffield, Director of the Australian Commonwealth Solar Observatory at Mount Stromlo and formerly professor of physics at University College, Reading.

Dr. T. Blackwood Murray, formerly chairman and managing director of the Albion Motor Car Co., Ltd., and a past president of the Institution of Engineers and Shipbuilders in Scotland, on June 11, aged fifty-eight years.

The Very Rev. Dr. David Paul, a past president of the Botanical Society of Edinburgh and of the British Mycological Society, on July 12, aged eighty-three years.

Dr. R. B. Riggs, Scoville professor emeritus of chemistry at Trinity College, Conn., and a member of the college faculty for thirty-three years, on May 11, aged seventy-three years.

Prof. E. M. Terry, associate professor of physics in the University of Wisconsin, known for his work on the effect of temperature on the magnetic properties of iron, cobalt, and nickel, and also on radio telephony, on May 1, aged fifty years.

News and Views.

THE formation of a committee for the excavation of Caistor-by-Norwich, which has followed on the publication of an air photograph revealing the street plan of the Roman town, affords Dr. R. E. Mortimer Wheeler an opportunity for some pertinent comments in the June number of *Antiquity* on the question of the exploration of Roman Britain. In the last few years the excavation of Roman sites in Britain has been extended remarkably. It has attracted a great deal of public attention and the discovery of Romano-British antiquities has become 'news' in the public press. As a consequence, appeals for funds are made more widely known and meet with a more liberal response. Caistor is only one of a number of recent cases in point. At present it is true this applies in some degree to all archæological investigation; but in Romano-British archæology, as Dr. Wheeler points out, much of this effort is wasted and misdirected. He suggests that Romano-British research should be more systematically organised. It is expected that the complete excavation of Caistor will cost at least £15,000, and this exclusive of publication, without which research is of little value for the general advancement of knowledge.

INTERESTING as it may be expected that the results of the exploration of Caistor will prove, there are other sites, especially those in urban or developing areas, which may be regarded as more urgently in need of excavation—such sites, for example, as Caerleon, Colchester, and St. Albans, where changing conditions may in a short time preclude all digging

This argument is sound; nor should too much weight be allowed to the opportunism which Dr. Wheeler recognises as a factor in determining the exploration of any given site. At present the scene of the archæologist's activities must be fixed largely by its capacity to arouse practical interest in the form of funds to meet expenses. This depends in part only on its scientific importance and more often than not local support is a paramount necessity. But this element of opportunism might be eliminated to a large extent. In the past, Roman Britain has been a highly technical study, and even now its problems of a more general character are only vaguely appreciated by the public. If the questions which await solution and can only be answered by the spade were more frequently stated on broad lines in surveys of the position at a given moment—surveys, for example, such as that recently published by Dr. Wheeler himself in *Discovery*—public interest would inevitably take a practical form which would make systematic investigation a possibility free from the fortuitous attraction dependent upon locality.

IT is with much interest we learn that the Foucault pendulum for demonstrating the rotation of the earth is to be re-suspended in the Science Museum. For many years Foucault's notable experiment was to be seen in the old galleries now occupied by the Imperial War Museum, and it always created great interest. In its new position it will be seen by many who have never previously heard of it. Foucault, who was born in 1819 and died in 1868, described his pendulum to the Paris Academy of Sciences in February 1851, but he had already erected one in the Paris Observatory. It was some years afterwards to be seen on the Champ de Mars. According to the "Life" of Frank Buckland, the naturalist, the experiment was first shown in England at the old Polytechnic in 1851, the year of the Great Exhibition, and Buckland himself that year, with the aid of two sons of Chief Baron Pollock, suspended a Foucault pendulum from the roof of the nave of Westminster Abbey, of which his father, William Buckland, the distinguished geologist, was then Dean. Foucault's second method of demonstrating the rotation of the earth, by means of the gyroscope, was described in 1852. It is from that our modern gyroscopic compasses and other similar instruments come.

IT seems possible that in a year or two we shall not only be able to speak to people in all parts of the world by telephone, but also to see a clear image of them showing the tint of their complexions and the colour of their clothes. Colour television was first achieved by Baird in England. According to a recent *Daily Science News Bulletin*, issued by Science Service, Washington, D.C., it has now been demonstrated more elaborately at the Bell Telephone Laboratories by Dr. Ives, whose father, Dr. F. Ives, of Philadelphia, invented one of the first and best methods of colour photography. In this method three photographs are made of the same scene. One is taken through a red glass filter and records all the objects coloured red, another records all the blues, and the third records all the greens. These are made into lantern slides, and in a triple lantern all three are projected on the same screen. Over the slide showing the reds is placed a red glass, over the one showing the blues a blue glass, and over the one showing the greens a green glass. The combined picture on the screen gives a natural colour reproduction. In ordinary television a group of photoelectric cells picks up varying light as the spots of the scanning disc show bright or dark areas on the object. The cell converts the moments of brightness into electric impulses which are transmitted by radio or by wire. In order to obtain colour television, we must use three groups of cells, one covered with a red filter, the second with a blue, and the third with a green. Red rays reflected from the object pass through a scanning disc and then through the red filter, and are stopped by the other filters. The electric impulse from the cells passes through vacuum tube amplifiers and over wires to the receivers, where it operates a glow lamp in front of which is a red screen, finally passing through another scanning disc. Similarly for the other colours, and we thus can get a combined image showing the natural colours. This development has been made possible by recent improvements in the manufacture of photoelectric cells.

THE two new short wave radio stations in New Jersey, U.S.A., for receiving and transmitting transoceanic telephonic communications have now been opened. Four channels from these stations are now in operation, two to Europe, one to South America, and one for experimental purposes. We learn from the *Bell Laboratories Record* for July that three frequencies are used, namely, 19,000, 14,000, and 9000 kilocycles respectively, corresponding to 16, 22, and 33 metres. Power for the transmitter is purchased from a supply company and is finally delivered into the line at 10,000 volts from a large rectifier. The antennæ consist of curtains of vertical and horizontal wires strung between towers 180 feet high and 250 feet apart. Each antenna is 500 feet wide and there are nine antennæ looped up end to end, giving a total length of 4500 feet. The receiving sets have two stages of radio frequency amplification, six stages of intermediate amplification, and one stage of audio amplification. The antennæ used at the receiving stations are also directive. The signals coming from the required direction are thus greatly strengthened, and those coming from other directions are weakened and thus cause little interference. In selecting sites for the receiving stations, great care was taken to avoid the proximity of motor-car and aeroplane routes, their unshielded ignition systems having been found to cause serious interference. As radio communication between aeroplanes and earth is now compulsory, their ignition systems will have to be shielded, and hence this cause of trouble is eliminated. Motor-car ignition systems are only shielded when a radio receiving set is carried on the car. Limits have therefore been assigned to the distance at which motor-cars can approach the stations. Horses are generally used for transport in their immediate vicinity.

IT is to be hoped that the development in Great Britain of the 'grid' system of high-tension mains by the Central Electricity Board will, amongst other things, materially help the farmer, but as R. E. Turnbull points out in an article in the *Nineteenth Century* for June last, the question is almost entirely an economic one, for unless the current can be supplied at a sufficiently low rate it will not pay the farmer to change over from the other sources of power which he has already installed. Further, electricity will naturally tend to be dearer in rural than in urban districts, as there are fewer consumers per square mile to share the costs of distribution. However, rural electrification has been carried out with great success in other countries such as Germany and Sweden, and it is stated on good authority that there is no fundamental reason why it should not be made a paying concern in England. In Canada also, the use of electricity is revolutionising both domestic and farm labour. It is particularly with regard to capital costs of transmission and distribution that England is at a disadvantage compared with other countries. Overhead lines, which on the Continent cost £150 to £200 per mile, cost as much as £600 to £800 per mile in England owing to Government restrictions. Competition with the gas industry and a local rather than a national method of dealing with the supply are other reasons why we are backward in our use of electricity. The lack of natural water power is not such a disadvantage as is often thought, for costly engineering works may be required before that natural power can be utilised.

A SCHEME has now been started in the Bedford area to test how far it is economically possible to extend the use of electricity in the rural districts of England. Active propaganda is to be carried out with the view of increasing the demand and awakening interest, demonstrations and hire or hire-purchase of electrical apparatus being included in the programme. Restrictions are being removed so that the cost of overhead lines will be less than £200 per mile, and it is thought that loss will be incurred for the first three years only. Similar developments will be made in other parts of the country if the Bedfordshire scheme proves successful. The wisdom of giving the farmer a subsidy on his crops has always been a debatable question, and it is suggested that a useful compromise would be found if a subsidy were granted to all authorities undertaking to supply electricity within their own rural area. The farmer would undoubtedly benefit, many other industries would obtain similar help, and new industries would tend to arise in the country districts, thus relieving the congestion in the towns. The farmer must in some way increase his output if he is to compete successfully with other countries. The use of electricity has been shown to achieve this, but in order to be an economic advantage the supply must be reasonably cheap.

THE jubilee of the Royal Zoological Society of New South Wales was celebrated on Mar. 24. Much water has flowed under the bridge since that date in 1879, when the New South Wales Zoological Society was formed "for the introduction and acclimatisation of song birds and game, and for other objects set forth in the prospectus". From the beginning the scheme had the support of the Government, and its donation of £500, together with private donations, allowed of the erection of aviaries and a keeper's house on 'Billygoat Swamp'. Gradually the gardens here expanded until, 11 acres in extent, they were found to be too cramped and unsuitable for their purpose. In 1911 the Government offered a choice of several new sites near Sydney, and Bradley's Head having been unanimously agreed upon, by 1913 £6000 had been expended and the new site had been cleared, fenced, and planted with some 2000 trees, shrubs, palms, and ferns. In 1916, when the enclosures were almost ready for the reception of the animals, the whole collection was transferred from the old Council to Trustees, and in 1917 the prefix 'Royal' was granted. The transference of the collections meant much more than a mere 'flitting', for since that time the Society has intensified its efforts to promote and advance the science of zoology. To this end it has worked with great success, as five volumes of the *Australian Zoologist*, as well as monographs on the fishes of New South Wales and the Australian Loricates, bear witness. The intensive study of the various branches of the science has been furthered by the establishment of specialised sections, and the monthly meetings of these are well attended and have stimulated research work both in the field and in the cabinet. We extend our congratulations to the Society on the good work it has accomplished and is carrying on for the behoof of popular and technical zoology.

A SURVEY of the utilisation of land in the county of Northampton has been published in three one-inch sheets by the Northamptonshire Education Committee. The survey was carried out by the pupils of the elementary schools of the county, under the guidance of their teachers and the general supervision of Mr. E. E. Field. The work was originally recorded on six-inch maps, and is now reduced to one-inch and printed by the Ordnance Survey. Three colours are used: light green for grassland, dark green for woods, and brown for cultivated land including rotation grasses and fallows. Building areas and mineral workings are uncoloured. The map is the first of its kind for a whole county, and is the sort of survey which is much needed in relation to various geographical and economic problems. Its construction must have been of great educational value to the children who took part, for it entailed an exploration of the region about the school and home and gave practical experience in the use of large-scale maps.

IN the June issue of *Sunlight* (Vol. 1, No. 8, p. 21), Dr. Vevers, the superintendent of the Zoological Society's Gardens at Regent's Park, London, describes the beneficial effect of fresh air and sunlight upon the animals. In the new monkey house, all the animals have access to the open air, the windows are of 'vitaglass', and in winter the cages are warmed by steam-heated panels and artificial sunlight is provided in the form of quartz gas-filled incandescent lamps.

By this means some of the most delicate monkeys and marmosets have been kept in perfect health through a severe winter. The effect upon the *moral* of the animals is also very noticeable. In the reptile house, similar good results have been obtained. The giraffes are among the latest zoo inmates to receive the benefit of artificial sunlight and radiant heat, and the success of the installation has been conspicuous.

THE disaster to the *Italia* airship off the north of Spitsbergen last year found Norway unequipped with any vessel of sufficient power and strength for navigation among heavy pack-ice. Appeal had to be made to the Soviet Government for the loan of an ice-breaker. The Norwegian government has now begun the construction of a vessel specially designed for ice navigation in view of Norway's interest in Spitsbergen. *La Geographie* for March–April gives some details. The vessel is to be some 230 feet long, with a beam measurement of 33 feet and a tonnage of 1275. It will be steam driven and both coal and oil burning. The engines will have 2000 h.p. and a speed of 15 knots is expected. The ship will have a cruising radius of about 7000 miles. There will be space for an aeroplane on deck. The ship is not to be primarily an ice-breaker, but it will be specially strengthened for ice navigation.

THE National Radium Trust has appointed Mr. P. Barter, of the Ministry of Health, Whitehall, to be secretary of the Trust, and Mr. Niven F. McNicoll, of the Department of Health for Scotland, to be assistant secretary.

MORE than six months before the opening of the next British Industries Fair, only five per cent of the total space in the new and enlarged Olympia, where the London section of the Fair is to be held on Feb. 17–28, remains unlet. In some trade sections of the London Fair there is no room left at all. The applications for space in the heavy section of the Fair, which is held simultaneously in Birmingham, are such that the question of further extensions is again becoming urgent. According to the scheme agreed upon by the advisory committee of the exhibitors in the London section of the Fair, the scientific section will be on the ground floor of the main hall, Olympia.

AT the tenth annual meeting of the American Geophysical Union on April 25 and 26, the following officers were elected—*Chairman:* Dr. Wm. Bowie; *Vice-Chairman:* Mr. L. H. Adams; *General Secretary:* Dr. J. A. Fleming. Sectional officers were elected as follows, the chairman, vice-chairman, and secretary being given in that order: *Section of Geodesy*—Mr. W. D. Lambert, Dr. L. J. Briggs, Mr. H. G. Avers. *Section of Seismology*—Mr. N. H. Heck, Dr. F. Wenner, Mr. F. Neumann. *Section of Meteorology*—Mr. G. W. Littlehales, Dr. W. R. Gregg, Mr. O. H. Gish. *Section of Terrestrial Magnetism and Electricity*—Mr. D. L. Hazard, Prof. L. W. Austin, Prof. H. W. Fisk. *Section of Oceanography*—Mr. A. H. Clark, Dr. H. B. Bigelow, Mr. H. A. Marmer. *Section of Volcanology*—Dr. A. L. Day, Mr. R. L. Daly, Dr. C. N. Fenner.

THE Secretary of State for the Colonies, with the approval of the Treasury, has appointed the following committee in accordance with section 1 of the Colonial Development Act, 1929: Sir Basil Blackett (chairman), Mr. Ernest Bevin, Sir John Eaglesome, Mr. R. H. Jackson, Sir Felix Pole, and Mr. Alan Rae Smith. According to the terms of reference the committee will "consider and report on, in the manner to be prescribed in the regulations to be made by the Secretary of State under section 1 (9) of the Act, applications for assistance from the Colonial Development Fund, in furtherance of schemes likely to aid and develop agriculture and industry in the Colonies, Protectorates, and Mandated Territories, and thereby promote commerce with, or industry in, the United Kingdom by any of the means specified in section 1 (1) of the Act". Mr. E. B. Boyd and Mr. C. G. Eastwood, of the Colonial Office, have been appointed respectively secretary and assistant secretary to the committee.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A teacher of electrical engineering in the Jarrow Secondary School—The Director of Education, Shire Hall, Durham (Aug. 16). A civil engineering draughtsman under the West Midlands Joint Electricity Authority—The Chief Engineer and Manager to the Authority, Central Administrative Offices, Phœnix Buildings, Dudley Road, Wolverhampton (Aug. 17). A keeper of the Art and Industrial Division of the National Museum, Dublin—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin, C.8 (Aug. 22). A lady guide-lecturer in the Leicester City Museum and Libraries—The Director, Museum and Libraries, The New Walk, Leicester (Aug. 24). A teacher of theory and design of structures at Goldsmiths' College, New Cross—The Warden, Goldsmiths' College, New Cross, S.E.14 (Aug. 26). An assistant in the Herbarium of the Royal Botanic Gardens, Kew—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1 (Aug. 26). A visiting teacher of chemistry and physics in its relation to photo-engraving at the L.C.C. School of Photo-engraving and Lithography—The Education Officer (T. 1a), County Hall, Westminster Bridge, S.E.1 (Aug. 27). An assistant curator at the Leeds City Museum—The Committee Department, Town Clerk's Office, 26 Great George Street, Leeds (Aug. 27). A chief inspector of weights and measures under the County Council of the West Riding of Yorkshire—The Clerk of the County Council, County Hall, Wakefield (Aug. 31). Junior assistants in the Metallurgy Department of the National Physical Laboratory—The Director, National Physical Laboratory, Teddington (Aug. 31). A junior lecturer in electrical engineering at the East London College—The Registrar, East London College, Mile End Road, E.1 (Sept. 1). A demonstrator in the Department of Physiology of the Middlesex Hospital Medical School—The School Secretary, Middlesex Hospital Medical School, W.1 (Sept. 1). An assistant lecturer in agriculture under the Cornwall County Council Education Committee—The Secretary for Education, Education Department, County Hall, Truro (Sept. 6). An assistant lecturer and demonstrator in metallurgy at the University College of South Wales and Monmouth-

shire—The Registrar, University College, Cardiff (Sept. 14). A director of the Ceylon Coconut Research Scheme—The Assistant Agricultural Adviser to the Secretary of State for the Colonies, 2 Richmond Terrace, Whitehall, S.W.1 (Sept. 14). A librarian of the National Library of Wales—Dr. D. Davies, Plas Dinam, Llandinam, Montgomeryshire (Sept. 28). Professors of surgery, medicine, and bacteriology in the University of Sydney—The Agent-General for New South Wales, Australia House, Strand, W.C.2 (Oct. 19). A laboratory assistant at the King Edward VII. School, Sheffield—The Head Master, King Edward VII. School, Sheffield. A full-time lecturer in mechanical engineering at the St. Helens Municipal Technical School—The Secretary for Education, Education Office, St. Helens. A technical office assistant in the Mechanical Department of the Egyptian State Railways, Telegraphs and Telephones Administration—The Chief Inspecting Engineer, Egyptian Government, 41 Tothill Street, S.W.1. A Grade "C" experimental officer at the Army Signals Experimental Establishment—The Superintendent, Signals Experimental Establishment, Woolwich, S.E.18.

Our Astronomical Column.

Brilliant Detonating Fireball on July 28.—This object made its appearance at 2 A.M. (summer time) on July 28 and was noticed by a number of observers who happened to be out of doors or looking from windows at the time. The object passed from over the sea north-north-west of Cornwall in a direction to south-south-east, and appears to have descended into the sea near Falmouth. Several observers describe the fireball as leaving a long, glittering train of sparks in its wake and as giving a loud detonation, which reached them soon after the light vanished. Some observers who did not see the actual flight of the object across the heavens thought the sudden illumination and thunder-like noise were due to an electrical storm; others thought an earthquake had occurred, for buildings in Falmouth were shaken and many people were awakened. The body of the fireball was of sensible size and seemed to one observer to have a diameter about twice as large as that of the sun. The whole countryside was lit up for two or three seconds and the full moon was paled into insignificance. The object must have penetrated to within a few miles of the earth's surface, for a few of the observers saw it apparently fall into the sea. Quite possibly it descended a little to the south-east of Falmouth, but further observations are required before the exact path can be ascertained.

The Observatories of Paris and Meudon.—*La Science Moderne* for July has an interesting article on the history of these observatories, with reproductions of old prints, one of which portrays Louis XIV. visiting the Paris Observatory shortly before its completion. It contained a museum, in which many early astronomical instruments were exhibited. It was Auzout who persuaded Louis that such an observatory was needed in France; the building was commenced in 1667 and completed in 1672, Perrault being the architect. Among the early observers we find the famous names of Cassini, Maraldi, Picard, Roemer, Huygens. Cassini here discovered the division in Saturn's ring, and four of its satellites, and Roemer made the first determination of the velocity of light. The reproduction of a woodcut made early in the eighteenth century helps us to realise the manner of observing with the enormously long refracting telescopes that were then in use; one was pivoted on the roof of the observatory, another on a high tower in the grounds. The article also describes the recent work at the two observatories, and gives a reproduction of one of Janssen's large-scale photographs of the solar 'rice-grains' on the scale of 1·20 metre to the sun's diameter.

The Nebula in Andromeda.—In the *Astrophysical Journal*, vol. 69, p. 103, Dr. E. Hubble continues his researches on nebulæ with a detailed study of the great spiral *M* 31, based on 350 photographs taken with the 60-inch and 100-inch reflectors at Mount Wilson. Owing to the size of the image, attention was concentrated on four regions giving a total area of about 40 per cent of the whole nebula. No indications were discovered of resolution into stars in the nuclear regions, though the outer and intermediate regions were partially resolved. Fifty variables were found, of which forty are definitely Cepheids with periods between 10 and 48 days. The latter show the period-luminosity relation conspicuously and give the distance of *M* 31 as 275,000 parsecs. The number of photographically observed novæ (previously 22) has been raised to a total of 87, and these form the basis of an interesting statistical discussion. A tentative comparison with the galactic system suggests that the latter is much larger than *M* 31, but that the ratio is not greater than that between *M* 31 and other extra-galactic systems.

Report of the Cape Observatory for 1928.—The report of His Majesty's Astronomer at the Cape has lately been issued. Upwards of 13,000 observations of right ascension and declination were made with the reversible transit circle. The stars under observation were: (1) zodiacal stars; (2) those south of declination −30° and not fainter than mag. 7·5; (3) Eros comparison stars for the near approach of that planet to the earth in 1930–1931. Heliometer measurements of the major planets were made near opposition, in continuation of the series commenced by Sir David Gill. A wide-angle lens, covering a field of 25 square degrees, with aperture 6 inches and focal length 80 inches, is under construction by Messrs. Taylor and Hobson of Leicester. This will be used for the construction of zone catalogues of stars from −30° to the south pole, on the plan inaugurated by Prof. Schlesinger. The Victoria telescope is being used for photographic determination of stellar parallaxes. 101 parallaxes are ready for publication, and material is available for determining about 100 more. Five parallaxes of more than a tenth of a second are noted, three of these being new. With the astrographic telescope, besides the ordinary programme, 14 plates were taken of Nova Pictoris, 9 of the bright comet 1927*k* Skjellerup, and 6 of Forbes's Comet. The repetition of the photography of the Cape astrographic zones has now been completed, and the determination of proper motions is in progress. It is stated that a series of photographs of Nova Pictoris, taken with the Victoria telescope using colour filters, show that the rings round the star are an optical phenomenon due to the peculiar distribution of light in the spectrum, and the colour-curve of the objective. The spectrum of the Nova in July 1928 was photographed with this telescope, using an objective prism in front of the object glass. It was a bright-line spectrum approximating to the Wolf-Rayet type. The continuous spectrum was weak; the line at λ4363 was strong.

Research Items.

Sinanthropus Pekinensis: Further Discoveries.—Further investigations by the Geological Survey of China at Chou Kou Tien during the season of 1928 have brought to light more *Sinanthropus* material from the site on which the type form molar tooth was previously discovered. The new material is described in general terms by Dr. Davidson Black in *Science* for June 28. It consists of the greater part of the right horizontal ramus of an adult lower jaw with the molar teeth *in situ* and having the premolar canine and distal half of the lateral incisor sockets preserved. Further, there are a worn right upper molar with evidence of injury during life, the labial side of the crown and portion of the root of a permanent median incisor, an immature lower median incisor and the root of a worn lower permanent median incisor posthumously crushed and deformed. All the specimens are deeply pigmented and mineralised. Though not found in the same deposit as the earlier material, there can be no doubt as to their contemporaneity and their geological age—Lower Quaternary (Polycene). The greater part of this material has still to be prepared and studied in the laboratory, but enough is now available to make it possible to draw certain conclusions. It is evident that *Sinanthropus*, like *Eoanthropus*, was a large brained form though the calvaria is not unduly thick. The morphology of the jaw of the two specimens presents features of unusual interest. The general architecture of the symphysis region makes it evident that the very generalised hominid dentition is supported with a framework of a type hitherto encountered only among forms having relatively formidable canines. The architecture of the jaw is much less hominid than that of the teeth; it supports and represents a type which, until the discovery of *Eoanthropus*, had been supposed to be associated only with an anthropoid type of dentition. It is clear, therefore, that distinctive hominid teeth were evolved before the supporting jaw lost its anthropoid form.

Is Evolution Continuous or Discontinuous?—Very considerable modifications have taken place in the views regarding the nature of Darwinian variations and mutations since these processes came into opposition as the alternative bases of the origin of species. Dr. Francis B. Sumner, in a short article in the July *Scientific Monthly*, summarises the present day point of view. He indicates that although the mutationists still 'stick to their guns', deductions from the results of genetic experiments, while allowing discreteness to the gene, have added to it a content of quantitative potentialities or values. So that mutation in the new view is no greater a 'saltation' than variation was in the old. It comes to this, apparently, that mutation is hereditary variation, regardless of magnitude, that is to say, it is a hereditary (transmissible) modification of the germinal substance, while the alternative variation is a non-hereditary change, due, as is commonly assumed, to the action of environment, broadly speaking, upon the individual. If mutation be regarded as of this minimal type, then evolution is due to a process which, while discontinuous in essence, produces a sensible continuity, for in the author's opinion the transition from one species to another has commonly involved no greater breaks in continuity than may now be observed between one individual and another in the same species.

Alcoholism.—The June issue of the *Bulletin of Hygiene* contains a review of recent literature on alcoholism, by Dr. J. D. Rolleston, whose previous contributions to this subject were noted by us last year (NATURE, Aug. 25, 1928, p. 285). The review deals with the historical aspects of alcoholism, its prevalence in Great Britain, France, Germany, Denmark, Russia, and the United States; its association with other morbid conditions, especially cancer, pellagra, and mental disease, experimental work, tests of drunkenness, mortality, legislation, and modes of prevention. A bibliography of 40 references to the literature of nine different countries is appended.

Changes in the Earthworm Fauna of Illinois.—Frank Smith records changes in the earthworm fauna of Illinois (*Bull.*, Div. Nat. Hist. Survey, State of Illinois, vol. 18, art. 10, 1928). The tendency is towards an increasing domination of European species and a corresponding decrease in the abundance of some indigenous forms. The author compares collections which he and others made thirty years ago with recent collections, and records that about 1896 only a few specimens of *Lumbricus terrestris* were seen in a restricted locality near Champaign crawling about during a rain storm. For several years afterwards specimens of this earthworm needed for class-work had to be obtained from dealers elsewhere, but about 1905 specimens were fairly abundant in the Arboretum in the University campus. Later the neighbouring area became abundantly stocked with them, while specimens of *Diplocardia communis*, which was formerly common, became infrequent. The area in Champaign into which *L. terrestris* has extended its distribution has also greatly increased in recent years.

Gas Vacuoles of *Arcella*.—The April issue of the *Quarterly Journal of Microscopical Science* (vol. 72, pt. iv.) is devoted to a memoir by the late Dr. Edward J. Bles on *Arcella*, and is a study in cell physiology. The experiments were devised by Dr. Bles and carried out with his well-known skill and care. He describes the morphology of *Arcella discoides*—the species selected for observation because of its transparent test, which is paler in colour, and flatter than that of *A. vulgaris*—and how he obtained a constant supply of young examples for study. The original object of the investigation was to determine the nature of the contents of the gas vacuoles in *Arcella*, and the author states that the gas is pure oxygen—if any other gas is present it is only in exceedingly minute traces. The oxygen is produced by oxidase action. The generally accepted view that the gas in the vacuoles is carbon dioxide is founded on a single experiment by Bütschli, and the author shows that this conclusion is untenable. The movements of pseudopodia from their protrusion to their disappearance are connected directly with the activity of an oxidase (the granules of which stain blue with benzidine), and on applying the benzidine test to several flagellates and ciliates it was found that a similar oxidase was present in them, and the author adduces evidence in support of his view that there is in these cases as in *Arcella* a similar method of converting the chemical energy of the oxidase action into the energy used in movement. The paper is illustrated by eleven plates of excellent drawings by Mr. A. K. Maxwell.

Evolutionary Sequence among Protophyta.—At the present time, eleven classes of simple, holophytic organisms are recognised, in no two of which do chromatophore pigments, reserve substances, and cell membranes show complete correspondence. In Fritsch's review of these classes under the title of "Evolutionary Sequence and Affinities among Protophyta" (*Biol. Reviews*, vol. 4, April 1924), it is brought

out very clearly that these classes may be regarded as parallel evolutionary series, most of which are represented by forms ranging from motile flagellate organisms to typical algæ types such as the chlorococcoid, filamentous, siphonaceous, etc. In fact, it is in only two of the eleven classes, the Euglenineæ and Chloromonadales, that typical algal forms are still unknown. In view of these facts, it is only reasonable to agree with Fritsch that the purely artificial distinction into Flagellata and Algæ should be abandoned. Recent work has also brought about a readjustment of the groups formerly included under the Chlorophyceæ. Borzi's original suggestion that yellow-green, oil-forming organisms should be placed in a class distinct from that containing the green, starch-forming organisms, has received ample justification and such forms are now classified as Heterokontæ —a group of equal rank with Chrysophyceæ, Bacillariales, etc. On the other hand, Bohlin's group Stephanokontæ, and Blackman and Tansley's Akontæ, do not receive equal support, and the tendency at the present time is to reduce these to the rank of subgroups co-equal with Ulotrichales, Siphonales, etc., of the large class Isokontæ, with the other sub-groups of which their metabolism is in agreement. The classification of the Isokontæ now appears to be satisfactorily established, but much work still remains to bring the other groups into an equally satisfactory condition.

Theories of Coral Reefs.—Wharton's view that foundations for coral reefs have been furnished by the marine abrasion of volcanic islands is shown by Prof. W. M. Davis to be untenable as a general explanation (*Science Progress*, July 1929). Darwin's theory involves slowly subsiding volcanic islands, and therefore uncliffed and bayed shore-lines would be expected, and such evidence as is available of the original foundations should reveal the slopes of a dissected cone. In contrast, Wharton's theory demands cliffed and non-embayed shore-lines, and uplifted reefs ought to be based upon flat platforms. It is shown that both Darwin and Wharton overlooked these and other inevitable consequences, but that, whereas Wharton's theory is found to be contradicted when it is confronted by the facts of exploration, that of Darwin is convincingly confirmed. The article is stimulated by a review of "The Coral Reef Problem", in which Prof. J. Stanley Gardiner suggests that Wharton's theory has not been proved untenable by definite evidence. Prof. Davis has now specifically answered this criticism in a paper which is not only a valuable summary of coral-reef evidence but also an admirable lesson in scientific method.

Continental Drift.—The attention of geologists is directed to a review of the continental drift hypothesis by Prof. Arthur Holmes (*Mining Magazine*, April, May, and June 1929). Evidence is summarised suggesting that the movements involved in the changes that have affected the face of the earth since the close of the Palæozoic include (*a*) a breaking up of Laurasia and Gondwanaland with a radially outward drift of the individual parts of each area towards the Pacific and the Tethys; and (*b*) a general drift, probably involving the whole of the crust, with a northerly component on the African side sufficient to remove Natal from the neighbourhood of the late-Carboniferous south pole and Britain from the late-Carboniferous tropics. It is shown that the motive force cannot be of external origin but must arise within the earth itself. What is required for (*a*) is a mechanism operating beneath the continents capable of stretching or splitting them and of dragging the parts away from each other. The radially outward movements suggest a system of convection currents generated by differential radioactive heating beneath each of the two great land-masses. The importance of recognising thermal and electromagnetic processes as well as those due to gravitation is emphasised.

Effect of Nuclear Spin on Spectra.—The line spectra of bismuth and cæsium have a hyperfine structure, the description of which falls outside the usual quantum theory of electronic motions. Stated formally, it requires the introduction of a new quantum number, and the corresponding physical accompaniment of this in the atomic model has been traced to the quantised rotation of the positive nucleus. The development of this idea on the quantum mechanics has been carried out by J. Hargreaves in a paper appearing in the July issue of the *Proceedings of the Royal Society*, for the relatively simple case of a nucleus with a half-quantum spin in an atom with a central field. After some empirical adjustment, the results of theory and experiment can be made to agree, and there emerges, *inter alia*, a rule for the most probable type of transition, namely, one in which there is reversal neither of the spin axis of the nucleus, nor of that of the electron which is responsible—loosely speaking—for the emission of radiation. Mr. Hargreaves suggests that some of the effects observed indicate that the charge of the nucleus is localised chiefly in its outer parts.

Raman Effect for X-Rays.—When homogeneous X-rays are scattered, some of the deviated quanta form a group which has hitherto been supposed to be of the same frequency as the incident beam. A careful analysis of this so-called unmodified radiation by D. P. Mitchell with a spectrometer of very high resolving power (*Physical Review*, vol. 33, p. 871) has now shown, however, that it is actually not homogeneous, but possesses a fine structure. The detail of the latter depends upon the nature of the scattering material, but is independent of the angle of scattering, and it is found that the changes in frequency correspond fairly well with characteristic frequencies of the atoms responsible for the scattering. The effect thus appears to be analogous to that discovered in the region of optical frequencies by Raman and Krishnan, except that the transitions involved are electronic in the case of X-rays, and molecular for the Raman spectra. It is perhaps somewhat difficult to picture how, as has been observed in one instance, the frequency of an X-ray can be increased by electronic scattering, and it also seems necessary to assume that when an X-ray has its frequency diminished, the electron concerned is only taken to the periphery of the atom, and then left there at rest.

A Simple Audio-Frequency Oscillator.—Most laboratory courses in physics and chemistry include electrical bridge measurements for which an alternating current supply is needed, and it is a common experience of instructors that these often prove extremely troublesome to operate. Mr. C. W. Oatley has described a low-power audio-frequency oscillator in the July number of the *Journal of Scientific Instruments*, which appears to be a considerable advance on previous pieces of apparatus used for this purpose. It consists essentially of a valve-maintained tuning-fork, of the type introduced by Dr. Eccles. The alternating voltage from this is taken to benches round the laboratory, and is amplified by a single-valve circuit on each, the bridge terminals being finally connected to tapped transformers on the anode circuits of the latter. A special feature

of the circuits described is that the only source of power required, both on the high-tension side and the low-tension side of all the valves, is the 110 volt D.C. main. In the actual circuit for which the details are given in this paper, the fork has a frequency of 180 cycles per second, and yields immediately 10 volts r.m.s. The maximum voltage which can be used on the bridge is 30 volts r.m.s., but Mr. Oatley's arrangements would appear to be susceptible of considerable modification, and apparatus similar in principle could be readily set up in most laboratories.

Crystallisation.—We have received from Dr. F. H. Maberley a note on a simple experiment in which half a stick of 'meta-fuel' is set on edge on a penny resting on a cork, is ignited and three-quarters allowed to burn. It is then blown out, and the sublimate collecting is examined with a lens. It consists of delicate crystalline needles, some with branching ends.

Oxidation-Reduction.—The twelfth (1927), thirteenth, and fourteenth (1928) of the series on this subject being issued by the U.S. Public Health Service, which were referred to in NATURE of Aug. 3, p. 213, have recently come to hand. A reply is made to Kodama's criticisms of the author's work on the Schardinger reaction, the previous results being confirmed. The thirteenth paper describes the preparation of 34 indophenols, many of which are new; all can be used as oxidation-reduction indicators, but nine are listed as being specially useful. The fourteenth presents data on the equilibrium potentials of four of the new indophenols, which are all rather easily prepared and have useful properties as indicators of oxidation-reduction. The potentials of three of the compounds lie at the electropositive end of the series, two of them extending the range beyond the limit previously reached with satisfactory reversible indicators. A revised list of useful oxidation-reduction indicators is also presented with their equilibrium potentials between pH 5·0 and 9·0 at intervals of 0·2 pH.

Solubilities of Calcium and Magnesium Carbonates in Water containing Carbon Dioxide.—The solubilities of calcium and magnesium carbonates in water containing dissolved carbon dioxide under varying pressures have been measured by Frear and Johnston and by Kline, respectively, and their results are stated in the July number of the *Journal of the American Chemical Society*. These authors give a critical summary of the work on the solubilities of the two substances in pure water at various temperatures and then describe experiments with water containing carbon dioxide. It is found that the concentration of calcium carbonate in solution is very nearly proportional to the cube root of the partial pressure of the carbon dioxide. The effect of the simultaneous presence of calcium sulphate was also investigated. In the case of magnesium carbonate, this was found to be stable down to a partial pressure of carbon dioxide of 0·004 atm., below which the hydroxide was stable. No indication of definite basic carbonates was obtained. The results are of importance in connexion with the use of hard waters in steam boilers and also in the theory of the formation of mineral deposits.

Heating Systems.—*Bulletin* No. 189 of the University of Illinois is the sixth dealing with an investigation of warm air furnaces and heating systems which is being conducted by the Engineering Experimental Station of the University in co-operation with the National Warm-Air Heating Association. A 3-story house has been built and equipped for testing at a cost of £5000, and the present bulletin deals with work carried out in this house by Profs. Willard, Kratz, and Day. It covers tests of efficiency, capacity, rating, and heat losses of commercial furnaces, heat insulators, sizes, positions, and resistances of air ducts, and the effects of conditions outside the house on their action. Six varieties of solid fuel have been compared, two types of chimney stacks and stove pipes, and the effect of providing thermal insulation in the ceiling has been determined. The loss of heat from the outside surfaces of the walls and windows and the influence of sunshine on it are to form the subject of a future bulletin.

Martinsel Steel.—Any improvement in the quality of steel for ships enabling scantlings to be reduced is welcomed by shipowners and shipbuilders. Among the new steels available is martinsel steel, which is referred to in a short article in the *Engineer* for July 19, by Mr. P. G. Rouse. The development of this steel was described in a paper read on Mar. 22 to the West of Scotland Iron and Steel Institute by Mr. F. G. Martin, who some seven years ago advocated the heat treatment of ship steel and the careful measurement of its elastic limit. It has been found that the elastic limit of steel depends on the arrangement of its microstructure, and this in ordinary ship steels is affected by the rolling. Martinsel steel is a special quality steel subjected after rolling to a special heat treatment ensuring the formation of a microstructure most favourable to the greatest elastic strength of the steel, and Mr. Rouse gives microphotographs of ordinary mild steel and the martinsel steel. Martinsel steel has been adopted by Messrs. Alfred Holt and Co. for their ships, and it is being used for the topsides and deck structure of the liner *Empress of Britain* now being constructed for the Canadian Pacific Steamships, Ltd. It allows a reduction of up to 12½ per cent in the thickness of certain parts. High elastic limit steel is also being considered for large bridges in which the saving of dead weight has a cumulative effect.

The Coefficients of Relativity.—In a short paper read before the meeting on June 21–22 of the Physical Society of America, Prof. S. R. Cook, of the College of the Pacific, Stockton, California, proposes to replace the well-known equations of the special theory of relativity, namely,

$$\left.\begin{aligned} x'=\beta(x-vt),\ y'=y,\ z'=z,\\ t'=\beta\left(t-\frac{vx}{c^2}\right);\end{aligned}\right\}$$

by the following set

$$\left.\begin{aligned} x'=\beta^2(x-vt),\ y'=\beta y,\ z'=\beta z,\\ t'_x=\beta^2\left(t-\frac{vx}{c^2}\right),\ t'_y=\beta t,\ t'_z=\beta t;\end{aligned}\right\}$$

where in both sets β denotes $(1-v^2/c^2)^{-\frac{1}{2}}$. The second set of equations introduces a transverse time as well as a longitudinal time, and is said to imply that clocks moving transversely to the direction of motion run more slowly than when at rest, but not so slowly as when moving in the direction of motion. The chief object of the communication, it is stated, is to inquire into the specific reasons for the universal adoption of the Einstein-Lorentz equations rather than those suggested by Prof. Cook. But in view of the facts that the Einstein-Lorentz equations are simpler, that they involve the two systems corresponding to the dashed and undashed letters in a perfectly reciprocal manner, and that their consequences have been very fully investigated, one cannot help feeling that before they can be given up a great deal more evidence must be furnished than is available in Prof. Cook's paper, which is described as a preliminary note.

Geology in Great Britain.

THE *Summary of Progress* for the year 1927 of the Geological Survey of Great Britain appears in two parts. Part I.[1] contains the Annual Report of the Geological Survey Board and of the Director. Eighty maps were published during the year, together with a number of memoirs, most of which have been already noticed in our columns (NATURE, Feb. 11, 1928). Among the new developments are the inception of a programme of geophysical work with the Eötvös balance; the authorisation of the sale of photographic copies of six-inch manuscript maps; and the opening out of a new district, the Orkney Islands. The volume also includes the field reports of the district geologists; an account of the petrology of the Cheviot rocks by Dr. H. H. Thomas; and details of nineteen new chemical analyses of rocks.

Part II.[2] contains thirteen original papers on British geology, thus extending in a welcome form last year's important innovation. Dr. W. E. P. M'Lintock and J. Phemister give an account of their gravitational survey along the line of the Swynnerton Dyke in Staffordshire; their investigation shows that in the proper hands this method is capable of affording valuable evidence regarding the situation and form of deep-seated rock-bodies. There is an interesting discussion relating to the origin of Cumberland iron-ores. E. E. L. Dixon attributes the hæmatite to a magmatic source, a hypothesis that is opposed by Bernard Smith. A new discovery of Lower Carboniferous basalts in the Lockermouth area, Cumberland, is described by T. Eastwood. The remarkable structures known as 'Ptygmatic Folding' have been found in great variety by H. H. Read in Sutherland, and he gives a valuable survey of various hypotheses that have been advanced to 'explain' them. There are also papers on the Yorkshire and Kent coalfields; on the geology of Manchester as exhibited in a tunnel; on new fossils from the Coal Measures; and on deep borings in the south-east of England and in Yorkshire. Altogether, this is a most valuable and stimulating publication which should be in the hands of every British geologist, whether he be an amateur, an honours student, or a teacher. The Survey is to be congratulated on having introduced such a medium for personal contributions and on having issued it at an attractive price.

To petrologists the most noteworthy publication of last year was Dr. Tyrrell's memoir on Arran,[3] a classic area which in Tertiary times was one of the great centres of igneous activity in the west of Scotland. This is the first complete account of the geology of the island. Though based on the descriptions of the northern two-thirds, which were included in Sheet 21 of the one-inch map of Scotland (1903), the treatment is unified and embodies the results achieved by many competent workers, including Mr. E. B. Bailey and Dr. Tyrrell himself, since that date. The earlier chapters deal with the crystalline schists of the north; with the black shales and spilites of Glen Sannox, which are reasonably assigned to the Lower Ordovician; and with the Carboniferous and New and Old Red Sandstone formations. The succeeding and greater part of the memoir is devoted to a detailed account of the Great Central Ring Complex and of the varied major and minor intrusions. Here there is much that is new, structural, petrological, and chemical, all replete with interest and scientific importance. Statistics of 525 dykes are presented, showing that the total extension of the crust in the east-north-east—west-south-west direction amounts to 5410 feet in 14·8 miles. In Mull the corresponding figures are 2504 feet in 12·5 miles.

The district described in the Northumberland memoir[4] includes Holy Island, the Farne Islands, and the delightful stretch of coast north and south of Bamburgh Castle, and extends inland to the edge of the Cheviots. The stratigraphy of the Lower Carboniferous and the tectonics are dealt with in greater detail than was formerly practicable, but it has been found that much of the earlier work by Gunn has required little or no revision. Important additions have been made to the chapter dealing with the Whin Sill and associated dykes, and the glacial deposits also receive more extensive treatment. There is a useful glossary of the local and mining terms of North Northumberland.

Part II. of the Wrexham memoir[5] continues the description of an area that includes the densely populated belt of the Denbighshire coalfield. The older formations were dealt with in Part I.; here the Coal Measures are described in detail with fossil lists, particulars of important shaft and boring sections, and a valuable account of tectonics. After a short chapter on the Triassic deposits, there follows a fascinating account of the mantle of glacial drifts left over half the area by the Irish Sea and Welsh ice-sheets. Mineral deposits and water supply are also adequately described.

The area covered by Sheet 153[6] is situated on the border between Staffordshire and Shropshire, and within it lie Wolverhampton and Lilleshall and an interesting stretch of the Severn Valley below Ironbridge and Broseley. The memoir is notable as being the first survey publication to describe the geology of the Coalbrookdale Coalfield. The solid-rock sequence described ranges from the Uriconian to the Triassic. Here again considerable attention is devoted to tectonics. The glacial and later deposits are significant of marked geographical changes, culminating in the development of the Severn gorge at Ironbridge.

The next memoir[7] to be noticed includes the towns of Ramsgate, Margate, Sandwich, Deal, and Dover, and covers a district that is well known for its coastal scenery and its excellent exposures of the Chalk. The work of the late Dr. A. W. Rowe on the succession of characteristic fossils has made this coast one of the younger classics of British geology. There is a short account of the concealed geology, but the memoir—and the new colour-printed maps—will be chiefly appreciated as an indispensable guide to the geology of a popular coastal district.

Prof. Boswell's memoir[8] describes the geology of a region that has long been an attractive field for geologists and students of the prehistoric periods of mankind. The neighbourhood of Woodbridge and Felixstowe is well known for its fine exposures of Crag de-

posits, and the labours of Mr. J. Reid Moir have disclosed numerous examples of what may be primitive implements. The area, which extends from Aldeburgh to Harwich Harbour, is now represented by two of the new series of colour-printed maps.

The next three memoirs belong to a county series in which the sources of underground waters are described in considerable detail. The Warwickshire volume [9] gives a general account of the geology of the county, and of the water-bearing strata and springs. Leamington Spa and the water supplies of Birmingham and Coventry receive special attention. An excellent coloured geological map accompanies the Somerset memoir,[10] which gives particulars, like the others, of all the principal deep wells and borings, with the geological classification of the strata passed through. There is a full bibliography of the mineral waters of Bath. There have been two previous volumes issued on the water supply of Sussex, but the new memoir [11] now published brings the account of the water resources and borings up-to-date by the addition of much new information. All three memoirs contain analyses of the waters, and will prove invaluable to engineers and others in search of underground supplies.

There remains to be mentioned a useful list of geological photographs,[12] arranged under subjects, which has been compiled from the complete set of more than 7000 subjects accumulated by the Survey during the last thirty years. The list has been prepared to help teachers and the public in general towards a proper and rapid selection of the more instructive and striking photographs. Copies, either as prints, enlargements, or lantern slides, can be purchased on application to the Director of the Survey.

The Forests of the Andaman Islands.

THE forests of the Andaman Islands were first reported on in 1866 by Mr. S. Kurz, Curator of the Herbarium of the Royal Botanic Gardens, Calcutta. At the instance of the Government of India, Mr. Kurz was deputed to explore these forests by Dr. Anderson, at the time superintendent of the gardens. Whilst recommending, in his interesting report, a certain amount of forest clearing for the extension of agriculture, and in order to render the settlement healthier, Kurz stated that, in his opinion, it was of the highest importance that the forests should be preserved, as they should have a considerable future value. Since the publication of this report the management of the forests of the islands has had a somewhat chequered career, but throughout a recognition of their value has persisted. The report on a recent "Tour of Inspection of the Forests of the Andamans" by Mr. A. Rodger, Inspector-General of Forests to the Government of India, should prove interesting reading to all having a knowledge of these interesting islands and their arborescent flora, so far as it is known (Calcutta: Govenment of India Central Publication Branch, 1928). The difficulties of working dense tropical forests by means of convict labour, and peopled in parts by an indigenous race of hostile people, need scarcely be emphasised; whilst the marketing of the products, even of so fine a timber as the padauk (*Pterocarpus dalbergioides*) has been fraught with unforeseen troubles. Mr. Rodger's report, however, goes to show that a turning point has been reached; and given the hearty and maintained support of the Government of India, which nowadays includes the Legislative Assembly and the Standing Finance Committee, these forests should become the source of an important export trade.

For many years, when the Andaman forests were alluded to, the average person thought only in terms of padauk, the sole timber then exploited. Other species, for trade purposes, were negligible. No less than fourteen different timbers are mentioned in the report, of which *Sterculia campanulata* is exported to Calcutta and Rangoon for match-making; Gurjan (*Dipterocarpus turbinatus*, *Griffithii*, *incanus* and *costatus*) to England, Madras, and Calcutta; the white chugalam (*Terminalia bialata*), which is in much demand as the source of silver grey wood; whilst the use of padauk is almost world-wide. A systematic survey of the forest crops for stock mapping purposes is now in progress, whilst a logging engineer has reported on the possibilities of introducing mechanical extraction to supplement the elephants and buffaloes at present employed. The engineer estimated that there are some 1870 square miles of forests which carry enough tonnage of timber per acre to make mechanical extraction possible. Even at the low figure of 20 tons per acre, this would give more than 20 million tons; and with a hundred year rotation an annual extraction of about 240,000 tons would be possible, or about nine times the present output.

The Inspector-General of Forests states that a rotation of a hundred years would be too short to produce the requisite sizes of the valuable species such as padauk, gurjan, and white chugalam; but, he adds, it must be remembered that the forests are full of over-mature timber which is certainly deteriorating, and should consequently be extracted as soon as possible. There would seem to be, therefore, every inducement for the Government to sanction the sums necessary for the introduction of the new methods of extraction recommended; the more so since the persistent efforts of the Forest Department have succeeded in placing on the market other species besides padauk, and that an increasing demand appears fairly certain.

On this head Mr. Rodger writes: "I have little doubt that the markets for Andamans hardwoods in India and England, and possibly also in South Africa, Mesopotamia, and elsewhere, can be gradually developed until we have an assured and profitable trade. . . . I look forward to the time when the very extensive mangrove forests of the Islands will be of value. Containing as they do as much as 160 tons of timber per acre, being most accessible and easily worked, it seems reasonable to imagine a time, not very distant, when the fuel market of Calcutta, now hard put to it to find enough fuel in the Sundarbans, will obtain its supplies from the Andamans. I understand that modern plant has been erected in the Philippines for the manufacture of tannin, wood alcohol, and charcoal from mangroves, and I see no reason why this should not be done in the Andamans."

The explorations now being carried out in these forests should produce fascinating results both botanical and zoological; some of the sylvicultural work already undertaken, in plantations and so forth, offers possibilities of considerable success. Mr. Rodger is to be congratulated on his most interesting report: for restrained, as is the case with official reports, though its phraseology may be, it proves that opportunities for carrying out work and investigations of considerable value and interest lie to the hand of the Andamans Forest Officer.

University and Educational Intelligence.

GLASGOW.—Sir Donald MacAlister, who has been Principal and Vice-Chancellor of the University since 1907, is retiring from the principalship in October next.

THE American Association of Museums is carrying out a scheme, for which it has this year obtained a grant of 118,000 dollars, for the construction of museums in Yellowstone National Park. Since 1924, when it obtained a grant of 70,500 dollars from the Laura Spelman Rockefeller Memorial for the establishment of a museum in the Yosemite Valley, this association has been very active in prompting the exploitation of the educational and scientific opportunities offered by the American national parks. In co-operation with the Carnegie Institution of Washington and the National Academy of Sciences, it established an observation station and museum at Yavapai Point in the Grand Canyon National Park, of which Dr. John C. Merriam, president of the Carnegie Institution, declared that it presented "one of the greatest educational and scientific possibilities of America or of the world". Some of the universities, notably Princeton and Northwestern, regularly hold courses in these reservations, and the Federal National Park Service and California Fish and Game Commission have for some years jointly conducted a field school of natural history in the Yosemite district which supplements the lower division of the university courses in botany and zoology and, incidentally, utilises the services of students as public guides. Last year the Secretary of the Interior appointed a committee of eminent men to make a survey of the educational possibilities of the parks. An account of these developments is given in the February number of *School Life*.

THE Commonwealth Government has appointed a Committee to consider the question of establishing a National University at Canberra. While not desirous at the present time of establishing an undergraduate university, the Government is of the opinion that a post-graduate University for the encouragement of original research work would be of very great service to the country and might well be initiated in the immediate future. The Committee is desired to examine the whole position and to report to the Council for Scientific and Industrial Research concerning: (*a*) The constitution and government of the said university; (*b*) its relations to the Council for Scientific and Industrial Research and to such other appropriate Commonwealth institutions as have been or may be established at Canberra; (*c*) its relations to the existing universities in the States, having regard to the consideration that it should be designed to supplement their work and not to compete in the training of undergraduates; (*d*) the departments of learning suitable for cultivation in the proposed university and the order in which they should be undertaken, whether at the outset or in the future; (*e*) the provision of a research teaching staff and of all necessary means of teaching and research, including buildings, laboratories, libraries, etc.; (*f*) the power to grant research degrees and the conditions under which such degrees should be granted; (*g*) the problem of endowments and financial administration; (*h*) any further matters which may seem to the Committee to require consideration in connexion with the proposed undertaking. Sir David Orme Masson is chairman of the Committee and the members are Sir Thomas Lyle, Sir Henry Braddon, Sir Robert Garran, Mr. A. J. Gibson, and, *ex officio*, the Executive Committee of the Council for Scientific and Industrial Research (Sir George Julius, Dr. A. C. D. Rivett, and Prof. A. E. V. Richardson).

Calendar of Patent Records.

August 11, 1598.—Edward Darcy's playing card patent, dated Aug. 11, 1598, which was an extension for twenty-one years of an earlier grant made to Ralph Bowes in 1588, for the sole making, importation, and selling of playing cards, was the cause of the famous law-suit known as "The Case of Monopolies", in which the common-law distinction between a patent for an invention and a monopoly in restraint of trade was clearly laid down. "Where any man by his own charge and industry or by his own wit or invention doth bring any new trade into the realm, or any engine tending to the furtherance of a trade that never was used before and that for the good of the realm, that in such case the king may grant to him a monopoly patent for some reasonable time, until the subjects may learn the same, in consideration of the good that he doth bring by his invention to the commonwealth, otherwise not." The grant, the avowed motive of which was to prevent able-bodied persons who might go to the plough employing themselves in the art of making cards, was declared contrary to the law, and the patent void.

August 11, 1868.—One of the earliest practicable typewriters was the invention of John Pratt and was patented in the United States on Aug. 11, 1868. The machine, which had a vertically disposed type-plate, movable in two directions to bring the required character to the printing point by means of connexions from the key levers, never came into practical use, but it was exhibited and worked at a meeting of the Society of Arts in 1866, the year in which the British patent was sealed; and it is said that an account of this meeting, which appeared in the *Scientific American* the following year, was the direct incentive that led Latham Sholes to the invention of the first Remington machine.

August 12, 1794.—The first patent for a ball-bearing was the English one granted on Aug. 12, 1794, to Philip Vaughan, ironfounder of Carmarthen, for the bearings of wagon axles. The axle box, having a ball race corresponding to a groove in the axle, was provided with a detachable section, secured in position by a wedge, to allow the balls to be inserted and removed.

August 12, 1851.—The sewing machine patent of Isaac M. Singer was granted in the United States on Aug. 12, 1851. Though this was not the first commercially successful sewing machine—the credit for the invention of which must be given to Elias Howe, whose American patent is dated five years earlier—it was on Singer's patent that the world-wide industry of to-day was founded (cf. Calendar of Patent Records, April 26 and July 17).

August 12, 1861.—The Langen 'bell and hopper' for the charging of blast furnaces, in which a central member in the form of a plug seats downwards in the bottom of the hopper to close it instead of being pulled up from beneath as in the usual type, was patented in Prussia by Eugene Langen on Aug. 12, 1861. The invention produced excellent results, but has not had very extensive application outside Germany.

August 14, 1839.—The first photography patent was the English one sealed in the name of Miles Berry, the patent agent, on Aug. 14, 1839, for "A new method of obtaining the spontaneous reproduction of all the images received in the focus of the camera obscura", as communicated to him by J. M. Daguerre. Daguerre was refused a French patent in order that the invention might at once be given to the public, but he was granted a government annuity of 6000 francs for "la gloire de doter le monde savant et artiste d'une des plus merveilleuses découvertes dont s'honore notre pays".

Societies and Academies.

Dublin.

Royal Irish Academy, June 24.—**Brian Coffey** and **Hugh Ryan**: The action of alcoholic hydrochloric acid on certain unsaturated ketones. Alcoholic hydrochloric acid with α-benzylidene-methylethyl-ketone gave a crystalline substance, m.p. 195°-196° C. with formula $C_{22}H_{24}O_2$, from which a tribromide $C_{22}H_{21}O_2Br_3$, m.p. 171°-172° C. was obtained. Unlike α-benzylidene-methylethyl-ketone, it did not condense with either piperonal or methylethyl-ketone and was stable towards mild reducing or oxidising agents. It proved to be the dimer

$$\begin{array}{l} C_6H_5.CH.CH.CO.CH_2.CH_3 \\ \qquad\quad | \quad | \\ C_6H_5.CH.CH.CO.CH_2.CH_3. \end{array}$$

The same substance was formed by the action of stannic chloride on an alcoholic solution of the mono-ketone. In a similar manner α-anisylidene-, and α-piperonylidene-methylethylketones were converted into crystalline dimers melting at 199° and 202·6° respectively.—**Hugh Ryan, W. B. Cornelia**, and **Pierse Hurley**: The condensation of aldehydes with benzyl-acetoacetic ester. Mono-substituted acetoacetic esters react with aldehydes in the presence of alkali to yield alkylidene-alkyl-acetoacetic acids and alkylidene-alkyl-ketones.—**Hugh Ryan, Peter McGeown**, and **John Keane**: Some derivatives of γ-anisylidene-methyl-ethylketone. By the action of anisaldehyde on γ-anisylidene-methylethylketone in the presence of alkali, a crystalline di-condensation compound which melted at 88°-90° C. was formed. This substance appeared to be 1-methyl-4·5-dianisyl-cyclopenten (3)-one (2). From the latter compound, by the further action of anisaldehyde in the presence of hydrochloric acid, a tri-condensation derivative melting at 158°-160° C. was formed, which was probably 3-anisylidene-1-methyl-4·5-dianisyl-cyclopenten (4)-one (2). The same compound was obtained by the action of anisalde-hyde on α-anisylidene-methylethylketone in the presence of hydrochloric acid. By the interaction of γ-anisylidene-methylethylketone with benzaldehyde and piperonal respectively, similar di- and tri-condensation deriva-tives were prepared.—**Hugh Ryan** and **George Cruess-Callaghan**: Preparation and oxidation of flavindo-genides. By the action of aldehydes on flavanone in the presence of acid, flavindogenides were obtained. Oxidation of 3-benzylidene-flavanone with potassium permanganate gave a colourless crystalline compound which melted at 163°-164° C. and has not yet been identified.—**A. J. McConnell**: The brachistochronic motion of a dynamical system. In this paper the equations of the brachistochronic motion of any dynamical system, that is, the motion from one con-figuration to another requiring the shortest time, are obtained in various forms and the geometrical pro-perties of the brachistochronic curves are discussed in the manifold of configurations.—**S. B. Wigoder** and **R. E. Patten**: Some effects of Röntgen rays on seed-lings. X-rays inhibit the growth of germinated seed-lings. In broad beans both roots and shoots are stunted, while in barley the shoots are most affected. The degree of stunting varies with the age of the bean and the part irradiated. Microscopically, the number of cell divisions diminishes three hours after irradia-tion, but usually recommences, although sometimes abnormally, after six days.

Edinburgh.

Royal Society, July 1.—**R. A. Sampson** and **A. E. Conrady**: Description of three Huygens lenses in the possession of the Royal Society of London. These three celebrated lenses, of 122 feet, 170 feet, and 210 feet focal length, which have never been examined by modern standards, were borrowed from the Royal Society for that purpose. They were examined with a plane test plate, and the interferometer; the Hartmann test was also used, and the effect of inter-posing the lens in front of a six-inch telescope of ascertained perfection. As a result the mechanical methods of figuring and centering the surfaces prove astonishingly efficient. The quality of the glass, however, is hopelessly bad. A photograph, taken according to one of Huygens' own tests, namely, the so-called 'Foucault' test of an artificial star or point source, filling the whole lens with light, shows little but a tangle of veins. Investigation of the history of these lenses confirms the conclusion of P. J. Uylenbrock in 1838 that they were made by Con-stantine, the elder brother of Christian Huygens. A photograph of the signatures of the two brothers shows clearly that the signature on the face of each lens is that of Constantine.—**W. J. McCallien**: The metamorphic rocks of Kintyre. The metamorphic rocks of Kintyre belong to the following groups, which are arranged from north-west at the top to south-east at the bottom: Erins quartzite, Ben Lui schists, Loch Tay limestone, Glen Sluan schists, Green beds, Beinn Bheula schists and grits, Skipness schists. The Erins quartzite has not previously been recognised in Kintyre and the Skipness schists have hitherto been included in the Beinn Bheula group. The Cowal anticline is continued through Kintyre to Campbeltown, where the rocks bend eastward across the strike of the fold. To the west of Campbel-town the rocks are folded into the Campbeltown syncline. The schists and limestone of northern Kintyre reappear in the Mull schists. North of Campbeltown the Loch Tay limestone advances relatively farther to the east than the other groups. The structures and unusual associates of many of the groups can only be explained with the use of slides.—**T. M. Finlay**: The Old Red Sandstone of Shetland (north-western area). A wide variety of rock types is represented in this area. A sedimentary series, mainly sandstones, is faulted against the gneiss to the north and east, forming a deep synclinal trough. These sediments are, in part, greatly altered by a later intrusive complex, the contact rocks show-ing a high degree of hornfelsing. Their exact horizon in the Old Red is indefinite, as the only fossils found in them are plant fragments too badly preserved for identification. Interbedded with the sediments is a volcanic sequence, the members of which include basalts, a rhyolite, and andesites with associated tuffs. Both augite and hypersthene andesites occur. About half the area is occupied by an intrusive igneous complex. It is sheet-like in form, and includes rock types ranging from gabbro to granite. The final phase of intrusive activity in the area is repre-sented by a system of dykes cutting the complex. These may be of widely different age.

Paris.

Academy of Sciences, July 1.—**Marcel Brillouin**: The dynamic tides of an ocean comprised between two parallels. Law of any depth in latitude and longitude.—**P. Villard**: Associations of clouds.—**Ch. Gravier**: The secondary sexual characters of *Limulus*.—**E. Mathias** and **Ch. Jacquet**: The variations of the terrestrial field at the Station du Sommet of the Puy de Dôme. The field is stronger in the day than during the night: the minimum was about 130 volts; maximum, 184 volts.—**A. Marchaud**: Continuous curves of limited order.—**Z. Horák**: The fundamental problem of the absolute integral calculus.—**Miécislas**

Biernacki: The directions of Borel of meromorph functions.—Charles Platrier: Solids with respect to which a material system is submitted only to internal forces.—Jules Schokalsky: New comparative mean levels of the White Sea, the Baltic, the Black Sea, and the Pacific Ocean.—V. Fock: The equations of Dirac in the theory of general relativity.—Stefan Vencov: The critical potentials and low tension arcs in hydrogen. The four critical potentials are given as 11·5, 13·6, 16·5, and 29·7 volts, attributed to resonance of the molecule, atomic ionisation, dissociation of the molecule and dissociation followed by double ionisation respectively.—Mendousse: Measurement of the effective wave-lengths of screens utilised in pyrometry.—Mlle. W. Czapska: The Raman spectra of the para-, ortho-, and metaxylenes.—A. P. Rollet: The precipitation of manganese dioxide by electrolysis with an alternating current. In the presence of nickel, manganese is completely precipitated as peroxide by an alternating current, and this precipitation takes place whatever the nature of the manganese salt. The precipitate was proved by analysis to be $MnO_2 . H_2O$.—G. I. Costeanu: Batteries with a fused electrolyte. The battery: copper oxide, fused caustic soda, zinc. At 400° C., this cell has, in air, an E.M.F. of 1·322 volts.—Emile Rousseau: The displacement of iodine from an iodide by an oil solution of cholesterol or of ergosterol irradiated by sunlight.—E. Rinck: The densities of liquid sodium and potassium. The experimental results found, for temperatures between the melting points and 650° C., were for sodium $d = 0{\cdot}9835 - 0{\cdot}00026(t - 96{\cdot}5°)$ and for potassium $d = 0{\cdot}826 - 0{\cdot}000222(t - 62{\cdot}4°)$. These data can be used for calculating the constant of Lorentz's law applied to the system $Na + KCl \leftrightharpoons K + NaCl$.—René Dubrisay, Jean Trillat, and Astier: Suspensions of kaolin in various media. The deposits from solutions containing soda, lime, or sulphuric acid were examined from the point of view of composition and crystalline structure.—Ch. Bouhet: The elliptical polarisation produced by reflection at the surface of solutions of fatty acids in water. The results confirm the hypothesis of the orientation of the molecules perpendicularly to the surface of the liquid, in a manner completely independent of Gibbs's adsorption equation.—J. Cluzet and Kofman: The photographic effect produced by the sterols after exposure to ultra-violet light. The experiments described do not agree with the hypothesis of phosphorescent phenomena, but support the view that the effect is due to the production of gaseous substances by the irradiation.—L. Hugounenq and E. Couture: The photochemical activity of various sterols and the nature of their action. The cause of the phenomenon appears to be chemical, possibly the formation of ozonides of the sterols.—Paul Pascal and René Lecuir: Complexes derived from triazinetricarboxylic acid.—D. Ivanoff: True mixed organo-magnesium carbonates. The author regards the name of mixed organo-magnesium carbonate for the substance MgXO . CO . R as inexact, and considers it should be kept for substances of the type MgXO . CO . OR. The preparation of some substances of the latter type is described.—A. Lepape and G. Colange: The relation between the proportions of ozone in air from the ground level and of air from the upper atmosphere.—Pierre Auger and D. Skobelzyn: The nature of the ultrapenetrating rays (cosmic rays). There are two hypotheses concerning the origin of these rays, one that they are primary and arrive directly from cosmic space, or at least from the upper atmosphere, the other, that there exists an ultra-γ radiation not directly ionising, which gives rise to the secondary β-rays observed. The observations described agree best with the latter view.—Louis Dangeard: The Foraminiferæ enveloping ooliths and pisoliths.—Edouard Chatton and Mme. M. Chatton: The state of fasting, a necessary but not sufficient condition of the experimental conjugation of the infusorian *Glaucoma scintillans*.—L. Lutz: The soluble ferments secreted by the Hymenomycetes fungi. The phenolic constituents of essential oils and the antioxygen function.—G. Ramon and Robert Debré: Attempts at the immunisation of man by means of an anatoxin of the scarlatina streptococcus.—C. Levaditi and P. Lepine: The mechanism of the natural refractory state of the lower apes with respect to the herpeto-encephalitic virus.

Craftsmanship in Modern Industry.

IN the building of the Jewish tabernacle some 3500 years ago a very high order of skill was demanded, and implied not only all manner of workmanship in metals, stones, and wood, every kind of cunning work, but also wisdom, understanding, and knowledge. The spirit of Bezaleel has persisted down to this day, and there are still clever workmen, possibly more in Great Britain than in any other country, unspoiled by excessive specialism, highly trained in hand and brain, and of dependable character. But, as Prof. Marshall has observed, skill is a very elastic and relative term, and has varying standards according to the state of general education among a people, their progress in industrialism, and their gifts of mother-wit or native sagacity.

Of late years the view has rapidly gained ground that skill, as generally understood, is required in modern industry in ever-lessening extent; the demand for it declines at an ever-accelerating pace. That the division of labour, extreme specialism, mass production, and scientific management are predominant features of industry to-day is generally taken for granted, though possibly they are not so predominant as is sometimes imagined; and in the degree to which they have been adopted there is probably no doubt that they have involved an increase in the amount of unskilled and possibly monotonous work, both absolutely and relatively. In any event, we are told that the quicker the whole of industry adopts these principles the better, unless it would perish miserably; and when these principles have been adopted, then skill, as we ordinarily understand it, will have become an anachronism. Perhaps it would be better to perish. Certainly the social effects of any substantial decline in the amount or degree of skill demanded from the whole body of industrial workers, including herein clerks, salesmen, draughtsmen, etc., would be deplorable; and there is no need here to elaborate on the philosophy of work and all that it implies in development of character and much else. The paramount need of work of the right kind for every healthy human being is well understood in all its implications.

Faced with such an apparently dark and perilous outlook, somewhat akin to that portrayed by those who speak glibly of the so-called 'machine terror', the economist and student of industry must make it his business to examine thoroughly such alleged tendencies and impressions, and, avoiding vague generalisation unsupported by tangible evidence,

endeavour to get down to a quantitative basis, secure measurable data, and so place the whole discussion on a strictly scientific footing. If economics is the science it claims to be, it should be able to do this. On the assumption, which cannot always be fully acceded, as will shortly be shown, that skill is rapidly dying out, various remedial suggestions have been made; such, for example, as more frequent change of occupation in the factory—a common practice in the Ford works; also, with or without a shortening of the hours of repetitive work, greater opportunity in leisure hours for some form of handicraft or hobby or 'satisfying' recreative work. This latter is certainly in any case a meritorious movement and should be heartily encouraged, as in Italy, where concentrated attention is now being directed to what is called *dopo lavoro*, or after-work occupation.

There are other factors which would militate against the alleged decline in the demand for skill which have not been so much consciously or purposely introduced, but have developed or evolved as industry itself has developed. But to take full advantage of these new growths, it is of course necessary to widen our definition of industrial worker to include not only the men and women in the factory, but also those in the office, for example, the clerks, salesmen, draughtsmen, and other categories. For these must be included if the aggregate amount of skill is in question, and thus at this point we are entitled to emphasise very strongly the fact that these categories have grown enormously of late years, and are constantly growing in proportion as the need for highly trained men in these different spheres becomes more keenly realised. They are characteristic of the modern age: salesmanship and publicity in the olden days were unknown or existed in a very crude form; accountancy, especially costing, the keeping of factory records, and all the multifarious operations involved in the management of a modern factory were formerly almost non-existent, but require to-day large numbers of highly skilled men. Consider also the numbers now employed in the drawing office, the research department, on intelligence and other work, and it will be realised that in the vast complexity and super-organisation of modern industry there are an almost infinite number of openings for highly trained men. The demand for such men, indeed, is often said to exceed the supply.

However, it is not proposed to make too much of these new developments, or to rely on them entirely to refute the common assumption of decaying skill. They at least entitle one to say that skill is not necessarily reduced in the aggregate, but rather changed in direction. From the point of view of the skilled or cunning workman, in cases where he has not migrated into one of the many new openings noted above, there is no doubt that in the design and manufacture of the wonderful and intricate machinery by which alone mass production is possible, the skilled workman is finding an ever-widening field; and who can say that the present form of mass production, with possibly a maximum utilisation of unskilled labour, is the final form or development of modern industry? All things industrial are in flux and transition. No doubt it is difficult enough sometimes to discern very clearly whither we are travelling. At present, industry has brought about a vast number of opportunities for unskilled work requiring little or no training, and much of this work has been taken over by women who otherwise would not go to work at all, although a few more might go into domestic service than is now the case. The position of the male workers who alone, apart at least from the textile trades, can come into comparison between the present and the past in the matter of skill is to this extent almost unchanged.

Remarkable confirmation of this conclusion, so far as it concerns an industry where mass production is predominant, has recently been given by Mr. C. G. Renold, of Messrs. Hans Renold, Ltd., Manchester, in a recent paper in the *Economic Journal*, providing that quantitative basis so much needed in these discussions. The works' records include an analysis of employees classified according to skill at three different periods—1913, 1927, 1928. Skill is used in an industrial sense and includes the black-coated groups. It implies dexterity, knowledge, judgment, and takes something like two or three years to acquire under actual experience of the job. Tables are given showing, *inter alia*, (1) increase in craftsmen category; (2) reduction in semi-skilled machine operators and unskilled labourers owing to use of more elaborate machinery giving greater output with less manning, the increased use of skilled men on such machines, and more women for unskilled work; (3) less 'upper staff' and 'male clerical'; (4) large increase in number of women employed. Other tables give interesting data as to output per worker in relation to prices and wages, showing large increase in efficiency with consequently reduced costs and higher wages.

On the whole, the outlook for the skilled worker, using this term in the wide sense which is legitimate

or industry to-day, is not nearly so hopeless as night at first sight and on superficial grounds be thought. But it is vitally important not to rest too securely on this conclusion. It is sound enough, perhaps, so far as it goes, but the complexities and reverberations of industry go deeper and further. To the social philosopher it has long been patent that skilled labour is not now quite so satisfying or so intellectually stimulating as in the past, not because it has become less in degree or extent, but because the worker himself has changed and demands more from life. Therefore in weighing the satisfaction or mental stimulus to be derived from work, it is necessary to remember that a more highly educated type of artisan, enjoying all the modern educative facilities of travel, wireless, etc., will be much more sensitive to moral and intellectual influences, prevailing currents of thought and mysteriously floating ideas, than he was in the olden days. The skill and dexterity required of him in his work will be much but not all. But still Bezaleel remains among us: the man who puts his whole heart into his work and asks for nothing more.

The March of Mathematics.

Proceedings of the International Mathematical Congress held in Toronto, August 11–16, 1924. Edited by Prof. J. C. Fields, with the collaboration of an Editorial Committee. Vol. 1: *Report of the Congress; Lectures; Communications to Sections I and II.* Pp. 935. Vol. 2: *Communications to Sections III, IV, V, and VI.* Pp. 1006. (Toronto: The University of Toronto Press, 1928.) n.p.

TWO stately volumes commemorate the meeting of the International Mathematical Congress at Toronto on Aug. 11–16, 1924. Although the receding shadow of the War caused some notable absences, yet thirty-three nations, some of them newly born, from all parts of the earth, sent some 250 mathematicians, who made 249 communications carrying over the whole field of mathematical endeavour. Six sections were the basis of the classification, four covering the ordinary range of pure and applied mathematics, and the fifth and sixth devoted to statistics, actuarial science, economics, history, philosophy, and didactics. For myself, I presided at one sitting of one of the sections, and felt strongly the truth of the description (by a distinguished scientific worker) of all such congresses, that they assembled, both in extent of subjects and diversity of tongues, the last stage of the Tower of Babel.

Eight formal lectures, however, gave valuable surveys of branches of knowledge by savants, becoming rarer every day, capable of envisaging wide fields of mathematical endeavour. The names of the lecturers, Cartan, Dickson, Le Roux, Pierpont, Pincherle, Severi, Størmer, W. H. Young, are sufficient indications of the value of these addresses. It is, perhaps, invidious to select any one of them, but what could be more stimulating and more provocative than the lecture of Dr. W. H. Young on "Some Characteristic Features of Twentieth Century Pure Mathematical Research"? I will mention only two extracts.

"In proportion as knowledge of mathematical theories has increased, the interest in purely formal work has diminished even in England, which may perhaps be said to have been its last refuge. It has begun to be understood all over the world that a mathematician is only a calculator when he must be. He is by nature a creator, a poet, not an artisan, an architect, not a mere builder."

"The question nowhere arises in Pure Mathematics whether there is anything in Nature corresponding even approximately to a mathematical concept."

Perusal of this lecture is strongly recommended both to those who agree and to those who disagree with it. It was perhaps owing to its difficulty that a similar survey of applied mathematics was not possible. To one standing outside the field of pure mathematics, it seems that Fourier's oft-quoted "l'étude approfondie des lois de la Nature est la source la plus féconde des découvertes mathématiques" requires some extension. For while it is true that many branches of pure mathematics have arisen in this way, it is also true to say that many branches seem to languish and almost die until revived by some new physical theory, for example, the impulse given to Riemannian geometry by the theory of relativity, and is it not likely that recent quantum speculations will stimulate the study of matrices, normal functions, characteristic numbers of differential equations, etc.?

Cartan's lecture on "La théorie des groupes et les recherches récentes de géométrie différentielle" may be cited as an example of this statement. In this lecture the application of the theory of groups to non-holonomous spaces must have derived much of its vitality from the relativistic spaces of Weyl and Eddington, a problem which in the last few months has again been attacked by Einstein.

An instructive lecture by Severi on algebraic geometry gave a historical retrospect of this subject, especially from the characteristic Italian point of view, which can best be described in his own words. "On tient toujours en vue le but principal qui est

d'éclaircir la théorie des fonctions par l'intuition géométrique et de viser les propriétés fonctionnelles au-dessus du symbolisme qui, quoique instrument nécessaire de nos recherches, ne doit jamais constituer leur but final."

Prof. L. E. Dickson gave us an interesting account of a fundamental generalisation of the theory of algebraic numbers. In connexion with the integral quaternions of Hurwitz, it is perhaps not generally known that Sir W. Hamilton in 1856 found the greatest common measure of two quaternions. The fascinating story of Norwegian researches on the aurora borealis was the subject of a discourse by Carl Størmer. The interesting mathematical problem of the trajectory of an electric corpuscle in the field of a small magnet is fundamental in the theory, and many of the phenomena receive their explanation in these trajectories. Simple though this hypothesis seems, the actual calculations are extremely laborious. Prof. Størmer told us that more than 5000 hours have been spent in numerical calculations! Prof. Pincherle gave a lecture on linear functional operations, showing the wide applications of these operations, and Prof. Pierpont displayed an elementary treatment of non-Euclidean geometry, starting from the expression for element of arc.

Prof. Le Roux, of Rennes, gave an account of general theorems arising out of the solution of the equation $c^2\nabla^2 v = \delta^2 v/\delta t^2$, and noted an interesting fact that if a 'source' moves with uniform velocity in a straight line, the value of the potential depends on the *instantaneous* position of the source and not on its *retarded*. Sir J. J. Thomson's original solution of the movement of an electric corpuscle gave a potential having the same property and the electric force radiating from the instantaneous position of the corpuscle. The equivalent solution of Heaviside depended on the 'retarded' position.

When one comes to the communications, a dictum of the late G. H. Bryan comes to mind, that it would be as impossible for an individual to understand everything mathematical published at the present day as it would be to understand every language spoken on the earth. There we have some 1700 pages embracing six sections. The first and second sections—algebra, theory of numbers, analysis, and geometry—occupy nearly half the whole space of the communications. Many of them were concerned with investigations arising out of the definitions of hypercomplex whole numbers, whilst in geometry the influence of the relativity theory could be seen in various directions.

Section 3 deals with the group mechanics, physics, astronomy, geophysics. Speaking generally, the tendency was in the direction of the application of extended analytical machinery to known results. The subject of quantum mechanics of the period was practically absent. The engineering section and Section 5 (Statistics) seemed very much alive; their proceedings contain important contributions to modern problems, such as aerodynamics and ballistics. Apart from specialist researches, some general papers deserve mention, such as those on the influence of mathematics on the development of naval architecture (W. J. Berry), mathematics in industrial research (Messrs. A. P. M. Fleming and R. W. Bailey), the teaching of mathematics for engineering students (Sir James Henderson), the teaching of the elements of the theory of elasticity to engineering students (Prof. E. G. Coker).

In Section 6 mention must be made of two papers by F. Cajori: "Past Struggles between Symbolists and Rhetoricians in Mathematical Publications", and "Uniformity of Mathematical Notations—Retrospect and Prospect", and one by G. A. Miller: "History of Several Fundamental Mathematical Concepts". A paper on the use of mathematics in economic, social and public statistics, by Prof. A. L. Bowley, is another of those surveys which ought to be read by all who specialise in other branches. In these days, the track of the individual mathematician is becoming narrower. He wears metaphorical blinkers in order to concentrate his aim. The benefit of a congress consists partly in the fact that such mathematicians listen to general addresses (which otherwise they would probably never read) and may derive widened outlooks showing new lines of attack. Moreover, in his own particular section discussion on a specialised paper may introduce ideas quite unknown hitherto. On one occasion the chance mention of the name Ritz in the discussion on a problem in elasticity led to interesting researches regarding this (sectionally) unknown name.

A very interesting photographic engineering supplement to Section 4 will recall to many a very enjoyable and instructive trip to Niagara and the great Queenston-Chippawa power plants. Who can forget the merriment when the trolley-car 'sat down' for want of electricity and was just able to crawl past a 550,000 horse-power generating house?

The editing of this vast work of nearly 2000 pages was done by Prof. J. C. Fields with the assistance of an editorial committee. During the Congress, Prof.

Fields was untiring in his efforts to make everything smooth for visitors. He seemed almost to possess the gift of being in more than one place at the same time, and yet found time to communicate an important paper on " A Foundation for the Theory of Ideals ". When the Congress was over, however, the real hard work commenced. Mathematicians are notoriously difficult to edit. For the most part, their work is badly organised and notations are rarely consistent. Prof. Fields (later on assisted by Prof. Chapelon) had indeed a mighty task in producing the well-arrayed volumes in question. More difficult still, the cost of printing turned out to be double the original estimate; finances had to be found. All this was, however, successfully accomplished, but, it is no secret, a heavy toll was taken of his health, research work, and his personal finances. The result is a monument to the University of Toronto and the Royal Canadian Institute, on the invitation of which the Congress was held, and to the various contributors and collaborators. Praise must also be given to the University of Toronto Press for the excellent manner in which a difficult task has been accomplished.

A. W. Conway.

Plant Pathology.

(1) *Principles of Plant Pathology*. By Prof. C. E. Owens. Pp. xii + 629. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1928.) 23*s*. 6*d*. net.

(2) *Plant Diseases*. By F. T. Brooks. Pp. vii + 386. (London: Oxford University Press, 1928.) 21*s*. net.

(3) *The Scientific Principles of Plant Protection*. By Hubert Martin. Pp. xii + 316. (London: Edward Arnold and Co., 1928.) 21*s*. net.

(4) *Lectures on Plant Pathology and Physiology in Relation to Man: a Series of Lectures given at the Mayo Foundation and the Universities of Minnesota, Iowa, Wisconsin, the Des Moines Academy of Medicine, Iowa, and Iowa State College, 1926–1927*. Pp. 207. (Philadelphia and London: W. B. Saunders Co., 1928.) 12*s*. net.

Since the War, plant pathologists have not only done much valuable research, but also have found time to write numerous books on their subject, and library shelves which ten years ago had ample accommodation for future accessions are now cramped. The four volumes under review are, however, books for which space must be found.

(1) The work by Prof. Owens is a general text-book designed to meet the needs of undergraduate students in American agricultural colleges, but it could also be read with profit and interest by students of botany in academic institutions. It is divided into two parts, of which the first, about a quarter of the book, is devoted to a general account of the development of the science, the nature of disease in plants, and the principles underlying causation and control of disease. Part 2 is a consideration of specific diseases, classified etiologically, which have been selected for detailed study. The author takes a commendably wide view of the science of phytopathology, including diseased states brought about by unfavourable conditions of the plant's environment, and also those due to invasion by slime molds, bacteria, fungi, algæ, parasitic seed plants, nematodes, and viruses. Following the discussion of each disease are directions for its practical study and a series of pertinent 'review questions'.

The references are the weakest feature of the book, for, with few exceptions, American work only is cited. The book is finely illustrated, containing more than 200 good photographs and line drawings, many of which are original. Throughout, the author emphasises the underlying principles of the science, and one cannot help envying somewhat the students who have Prof. Owens for their teacher. There is certainly just as much true educational value to be derived from such a training in plant pathology as from the study of much that passes for 'pure science' in our teaching institutions. In spite of the American perspective of Prof. Owens's volume, it is a sound text-book and a useful addition to the literature of the subject.

(2) Prof. Owens writes from the point of view of a professor of plant pathology in a State agricultural college. Phytopathology is recognised as an independent science, having its foundations in botany, zoology, chemistry, physics, agriculture, and economics. The author is therefore concerned not merely with specific diseases, but also with the principles underlying causation and control of disease in plants and with the relation of plant disease to human welfare. Mr. Brooks's volume, on the other hand, is written from the point of view of a sometime president of the Mycological Society and a lecturer in botany in a university department, where phytopathology is not recognised as an independent science but as applied mycology, or merely one phase of botanical application.

In consequence, Mr. Brooks devotes very brief consideration to the principles and more general aspects of plant pathology, to diseases caused by

non-parasitic agencies, to preventive and control measures, and to the economic relations of the subject. His book is, in effect, a descriptive catalogue of the fungus diseases of plants with brief chapters on diseases caused by viruses, bacteria, actinomycetes, myxomycetes, and green algæ. To each of the chapters is appended a well-selected list of references.

The cataloguing is extremely well done, and, for its size, the book contains an astonishing amount of information. All the illustrations are original and some of them are good, but taken as a whole they are not of the quality of those in Prof. Owens's volume. The book is a handy compendium of the mycological aspects of diseases of British plants, and will be useful to all students and practitioners of the more comprehensive science of phytopathology.

(3) Mr. Martin's book is a detailed consideration of a field jointly occupied by phytopathologists and economic entomologists, and it is all to the good that a chemist should step in and summarise from his own point of view the data of *Pflanzenschutz*. Like Mr. Brooks, however, his purview includes only diseases caused by parasites, and the large and difficult, because diffuse and obscure, field of non-parasitic diseases, a field which in the last edition of Sorauer's "Pflanzenkrankheiten" has nearly 1000 pages devoted to it, is entirely omitted. The literature of the chemical aspects—less so of the pathological ones—has been keenly scrutinised; there are references to 116 different scientific journals, and the author index comprises seven double-column pages of names.

The book, in fact, is not merely a consideration of the scientific principles of plant protection, but is also an adequate synthesis of a considerable mass of experimental data, much of which is, otherwise, not easily accessible. The only criticism one would make is that the data are not always carefully selected. In his foreword, Sir Daniel Hall justly says: "There is a general theory of plant medicine and plant hygiene, and Mr. Martin's book is the first introduction to it that has appeared in English." The volume is essentially the contribution of a chemist to a field of research in which chemists must in the future enter more actively and personally than they have done in the past.

(4) To the more general reader the Mayo Foundation Lectures for 1926–27 on "Plant Pathology and Physiology in Relation to Man" will be the most interesting of these volumes. The contents, however, give the impression that four plant pathologists, one ecologist, and one physiologist were chosen, quite arbitrarily, and asked to give one lecture each on some subject coming within their own field of research—the particular topic not really mattering so long as it could be made to impinge on human welfare. The book in consequence has no coherent thread running through it; it is entirely sporadic, and makes no attempt to cover the field expressed in its title. The lectures vary from the nine pages of Prof. Cowles to the fifty of Prof. Coons or the fifty-eight of Prof. Stakman, and, whereas the former is a general talk, the two latter are technical essays. Both the latter equally need illustrations, as, indeed, do most of the essays in the book, yet one has sixteen excellent figures and the other none. A little judicious editing would greatly have improved this volume.

The first lecture by Dr. Kunkel on "Filterable Viruses" gives in simple language a good general notion of these obscure agents of plant disease. One is, however, surprised to hear the author bewailing his lack of diamond lenses, for there is a general impression that workers at the Boyce Thompson Institute possess such things as mere routine equipment. In his brief essay on "Ecology and Human Affairs", Prof. Cowles says some cogent things, and one could wish that more academic botanists would realise with him that "agriculture furnishes much of the best material for students of botany". The lecture by Prof. Coons on "Some Aspects of the *Fusarium* Problem" would be more congruous in a scientific journal. On the other hand, *Fusaria* are among the most destructive parasites of crops, and it is perhaps just as well that the general reader should have opportunity of gaining insight into the methods of study of parasites which exact a toll of his income. Prof. Stakman's discussion of "Racial Specialisation in Plant Disease Fungi" is noteworthy. The importance of hybridisation in the origination of new forms is at last being recognised, and there now remains to be recognised only the fact that single spore strains are not, necessarily, genetically pure. Both the latter essays contain extensive bibliographies which add greatly to their value.

Prof. Whetzel's lecture on "The Relation of Plant Pathology to Human Affairs" is a fascinating account of the development of the science. The importance of plant diseases may be realised from the author's statement that in the United States "approximately one bean in every dozen, one apple in every seven, one peach in every eight, one bushel of Irish potatoes in every twelve, and one bushel of wheat in every ten, are destroyed annually by

diseases in these crops". This very conservative estimate is probably true on average of the crops in the British Empire, and these losses are largely preventable. Such recurrent destruction of produce is scarcely conceivable in any industry other than agriculture, and if it did occur in, for example, engineering or shipbuilding, there would be no time wasted in discussing whether or not money could be afforded for research on cause and prevention; it would be provided forthwith.

Apropos of recent discussions in Great Britain on the training of biologists, one would like to quote Prof. Whetzel's forecast:

"We are only entering on the era of the professional plant pathologist. As yet most plant pathologists are employees of the State or federal government. Here and there, however, one is entering into the employ of commercial concerns interested in the control of diseases of plants: Farmers' organisations, nursery growers, smelting companies, manufacturers, and purveyors of fungicides and insecticides, and the like. The day will come when the sign of the plant pathologist will stand forth in the street alongside that of the physician and surgeon. This country can and probably will profitably support eventually more plant pathologists than physicians of medicine and surgery."

The last essay in this little volume is by Prof. Osterhout, on whom a portion of the mantle of that very great prophet, Jacques Loeb, seems to have fallen. The author deals with his illuminating researches on semi-permeable membranes, and manages to put obscure and difficult things into simple understandable language.

Altogether the book is one to fascinate any young student of botany or plant pathology, and opens to his view glimpses of the wider reaches of his subject. W. B. B.

Philosophy in Biology.

The Sciences and Philosophy. (Gifford Lectures, University of Glasgow, 1927 and 1928.) By Dr. J. S. Haldane. Pp. ix + 344. (London: Hodder and Stoughton, Ltd., n.d.) 15*s*. net.

PROF. HALDANE'S Gifford Lectures offer several points of special interest. In the first place, every reader will be struck with the reference which he makes in the preface to his older brother, Lord Haldane, and the debt of gratitude which he there acknowledges. In the second place, he gives a sufficient and illuminating account of his own researches in respiration and acclimatisation, fitting them in to his philosophic scheme. Thirdly, he has a full and most interesting account of what he understands by 'vitalism', with reasons why he does not call himself a 'vitalist'. Lastly, his lectures are the most perfect example in the Gifford series of a complete and coherent philosophy built round a definite scientific doctrine. What we have to say about the book may be conveniently grouped round these four points.

In 1883, J. S. Haldane was a medical student at Edinburgh, and a volume of "Essays in Philosophical Criticism", edited by his brother and Andrew Seth, afterwards Prof. A. S. Pringle-Pattison, appeared with contributions from both brothers. The book aimed at distinguishing the fundamental conceptions belonging to different branches of knowledge and was strongly Kantian or post-Kantian in tone. The younger brother, though a medical student, admits that his chief intellectual interest at that time was in philosophy. He had already conceived, under this philosophic influence, the bent against a mechanistic explanation of the phenomena of life which has remained with him throughout. These lectures are the mature outcome of this early training. The philosophical questions from which he started have been before his mind all through his scientific career, and he now attempts to present them as a connected whole, fortified by his scientific conclusions.

Prof. Haldane's own scientific experiments, which have filled the forty years and more since those Edinburgh days, are contained partly in ordinary scientific papers, partly in the two books "Mechanism, Life and Personality" of 1913 and "Respiration" of 1922. The results of these researches are skilfully and relevantly introduced into the chapters on the "Fate of Mechanistic Biology" and that on "Vitalistic Biology". Prof. Haldane takes his stand on the conclusion formulated by Claude Bernard that "all the vital mechanisms, varied as they are, have only one object, that of preserving constant the conditions of life in the internal environment". All the cases which he adds himself to those of Bernard are only further illustrations and corroboration of this general conclusion. Stating the matter broadly, we are forced to conclude that all the separate arrangements or pieces of so-called 'mechanism', by which the organism is kept in contact with its environment, whether internal or external, are regulated or adjusted to the right performance of their function, not by their own mechanism but by some general force, or principle, or agency, so that every part not only subserves the interests of the whole, but also is actually operated by the whole.

It will be said, of course, that this is only what is done in an ordinary man-made engine by a regulator introduced for that very purpose and that it only remains for us in each case to find the appropriate regulator in the living machine. Haldane's answer, and that, we presume, of all vitalists, would be that though we are constantly finding fresh pieces of 'mechanism', yet, pursuing this tack, we get no nearer, but rather further from, the connecting link; that life itself is the regulator.

The other great and obvious characteristic of the living being, that of reproducing itself, is clearly another aspect of the same activity. Granting, with this school of thinkers, that the maintenance and co-ordination of its specific character is the quality of life, then the prolongation of life beyond the activity of the individual follows as a part of the more general function. The special mechanisms by which this is accomplished are subordinate to the main object, just as the various mechanisms of respiration, excretion, etc., are subordinate to the general and constant maintenance of the individual being.

The third point, which we mentioned above, is probably that which will attract most criticism to the book from fellow-biologists. Why, it will be said, distinguish yourself from other vitalists when you agree with them in the substantial point, and only differ, partly from the older and crude view which no one now accepts, partly, as in the case of Driesch, from certain particular applications of the doctrine which may be mistaken without invalidating the main argument? On the whole, we think this criticism of the book and of the author's general position is sound, and that he should be ranked at least among the 'neo-vitalists'. But it is only fair to him, and interesting and enlightening in itself, to put his own ground for distinguishing his position from the vitalists as clearly and strongly as possible. It goes, in fact, to the root of his general philosophical position. He is not a vitalist in his own view, because he does not hold that we see in living phenomena some new force added to the physical and chemical process from without, but that we have in life all the physical and chemical processes taken up and looked at from another and higher point of view. The Newtonian or physical synthesis is thus abstract or provisional. We do not discard it when we advance to biology, but view the facts in another more comprehensive and higher aspect, nearer, in fact, to that highest conception of reality of which we are capable, when we take the last great step and reach the plane of consciousness. Prof. Haldane notes also that in the latest modifications of the Newtonian synthesis we seem to be approximating to the life-conception, even in the parts of our experience which we are accustomed to treat as belonging to the inanimate. On this he, while alluding to Prof. Eddington's recent volume of Gifford Lectures, wisely prefers to say as little as possible.

The last step completes the philosophical hierarchy of the scheme and brings the book into the sphere of metaphysics and religion from which, as the author tells us, he started as a young man in Edinburgh. The ideal of philosophic unity and completeness is the most striking feature of the whole work. As he began with it fifty years ago, so he comes back to it with the satisfaction and sense of rest gained from an ideal confirmed by experience. Detailed criticism of this part of the volume is more suited to other pages, but a brief indication of its purport is called for here. Just as in life we find another principle or point of view subsuming the purely mechanical, so in consciousness a still wider one completes the vital. Prof. Haldane represents this to himself as the integration of time-relations by the conscious mind as biology integrates those of space. Again we think that the biologists may find some cause for quarrel here, and again that the author may have a perfectly valid answer from his own premises. In biology we are concerned with how the organism now works; in psychology the whole process depends on memory, which involves the past, and interest, which looks to the future; and if the critic says, "But this must be true of all living things, and not only of our own minds", the author's answer is, "By all means. My philosophy contemplates life and consciousness as different in degree, but co-extensive with existence." Starting from this premise, or, if you will, this general conclusion, he breaks a lance with Smuts on holism, as he broke one with Driesch on vitalism.

The similarity of the general outlook with that of General Smuts's recent book will of course strike every reader, and Prof. Haldane admits the kinship. But he expresses strong dissent from Smuts on the point of the sudden and mysterious incursion of consciousness into the universe. If it is ever there, it has been there for ever. This stamps his philosophy and brings him at the close to his religion. The fact that so many notices, which have already appeared, find enough to say in criticising its contacts with religion, is evidence of the immense scope and profound interest of the book. It is morally inspiring, intellectually stimulating, substantially true. F. S. MARVIN.

The Parasitic Worms.

A Manual of Helminthology: Medical and Veterinary. By Dr. H. A. Baylis. Pp. xi + 303. (London: Baillière, Tindall and Cox, 1929.) 30*s.* net.

IT is rare indeed to find a text-book of general or economic zoology which treats of the parasitic worms without introducing some errors, often gross errors, although in dealing with the other phyla it may be strictly accurate. This, in the past, has been, in part at least, due to the fact that no good modern text-book on helminthology has been available. With the appearance of Dr. Baylis's work on the subject, that excuse is removed. In a matter of 300 pages, the author, briefly and concisely, provides such short descriptions of the genera and species of helminths of man, the domestic mammals and birds, as will, with the aid of the illustrations, enable the reader to obtain at least an approximate determination of most of the parasites which he is likely to meet.

The book falls into two parts, the first dealing with the flat-worms, and the second with the round-worms. Each part commences with a general account of the anatomy, then proceeds to consider, family by family, the parasites of medical and veterinary importance, their occurrence and morphology, and the more important facts of their life-histories so far as they are known. The clinical and pathological aspects of the subject are not considered and the volume is essentially a zoological one. The classification used is a natural one, so far as our present knowledge makes this possible; and in order to correlate the parasites of each host, a classified index to the parasites of the more important animals or animal groups is appended. The nomenclature used is up-to-date; but to avoid confusion with other names which have enjoyed long, though incorrect, use, the more common and well-known synonyms are usually given as well, the correct names being printed in heavy, conspicuous type.

There is no need to emphasise the importance of this subject in both medical and veterinary medicine, and helminthology is now an essential part of the curriculum of every student of these subjects, either as part of his initial training in zoology or as a separate course later on, or as both. There is accordingly a real necessity for an accurate, authoritative text-book such as this. It has its limitations; limitations set by the extent of present-day knowledge of the parasitic worms, by the omission of parasites of wild or partially domesticated animals (such as elephants and rabbits), and by the absence of pathological and clinical helminthology. To have included these, however, would have required a work of encyclopædic proportions, and correspondingly prohibitive price. Within these limitations, Dr. Baylis has done his work well and has produced a text-book of immense value, especially to those interested in zoological helminthology. The manual is well and clearly written, adequately illustrated, and strongly produced, and should meet with a ready response among zoologists, medical men, and veterinary surgeons.

Our Bookshelf.

Ibn Battúta, Travels in Asia and Africa, 1325–1354. Translated and selected by H. A. R. Gibb. (The Broadway Travellers.) Pp. vii + 398 + 8 plates. (London: George Routledge and Sons, Ltd., 1929.) 15*s.* net.

"THE Broadway Travellers" offers to the public in popular form a store of entertaining reading as well as a series of valuable records, many of which are not otherwise readily available. By including in this series the travels of Ibn Battúta, which are now for the first time made accessible to the English reader, the editors have earned the gratitude of all students of travel literature who are not professed orientalists. Ibn Battúta stands in the first rank of medieval travellers. As a Moslem he gives a picture of the eastern world which not only differs in perspective but is at the same time truer and more intimate than that of the European travellers of about his own time. Granted the difference in orientation, the general attitude of mind of this traveller is more readily comprehensible to the modern reader than that of the medieval Christian.

Ibn Battúta, who was born at Tangier in 1304, set out on his travels at the age of twenty-one. His aim was to accomplish the pilgrimage to Mecca, but he was diverted by circumstances and traversed the whole of Syria before reaching the Holy City. A visit to Iraq was followed by three years' theological study in Mecca, during which time he formed the project of visiting India, but before doing so he visited the trading stations of East Africa. Then India was reached by way of Asia Minor and Central Asia. After a stay of some seven years at Delhi he was sent as an envoy to China. When he returned to his native land after 1348 he had covered a distance estimated at 75,000 miles. He died in 1368 or 1369. The mere recital of the countries visited and the distances covered, however, gives a very meagre idea of the value of his record. His intellectual qualifications and standing as a qádi and his consequent interest in theology, combined with his intensely human personality, give his record an interest which is surpassed by no book of travel of his own and not many of a later day.

Fortpflanzung und Befruchtung als Grundlage der Vererbung. Von Max Hartmann. (Handbuch der Vererbungswissenschaft, herausgegeben von E. Baur und M. Hartmann, Band 1.) Pp. ii + 103. (Berlin: Gebrüder Borntraeger, 1929.) 9·60 gold marks.

Verteilung, Bestimmung und Vererbung des Geschlechts bei den Protisten und Thallophyten. Von Max Hartmann. (Handbuch der Vererbungswissenschaft, herausgegeben von E. Baur und M. Hartmann, Band 2.) Pp. ii + 115. (Berlin: Gebrüder Borntraeger, 1929.) 24 gold marks.

BAND 1 gives in compact form, and well illustrated, an account of the main phenomena of reproduction and fertilisation bearing on heredity, in the Protista and other groups of lower plant and animal organisms. Various terms not at present in general use, such as cytogony for cell reproduction, agamogony (gonidia formation), gamogony (gamete formation), gametanogamy and pædogamy are introduced. The chapter on the antithetic alternation of generations gives a useful series of diagrams in which the nuclear phases of *Cutleria*, *Scinaia*, Phycomyces, mosses, and other plants are compared.

In Band 2 the determination, inheritance, and distribution of sex in Protista and Thallophytes are described. Four types of sex determination and distribution are recognised, namely, phenotypic and genotypic determination in the haplophase and the diplophase respectively. This volume contains a very serviceable summary of the modern work on sexuality in Algæ and Fungi, much of which has not been brought together elsewhere. Scattered observations bearing on the subject in *Characium*, *Gonium*, *Gregarina*, *Actinophrys*, *Alaria*, Diatoms, and many other organisms are included. Numerous tables and diagrams in which the sexes are distinguished by colour make easy a comparison of conditions in different organisms.

Inorganic Quantitative Analysis. By Prof. Harold A. Fales. Pp. xii + 493. (London: G. Bell and Sons, Ltd., 1928.) 12*s.* 6*d.* net.

A TEXT-BOOK of inorganic analysis produced at this period which aspires to more than local interest must treat the subject from some new aspect. This object is achieved here by development from the physico-chemical side, somewhat on the lines of Bassett's "Theory of Quantitative Analysis". The scope of the present volume is, however, much wider in order that the whole field of analytical manipulation may be fully covered; for example, chapters are devoted to precision and to the theory and practice of weighing.

The exercises described are largely determinations such as are encountered practically; there are copious explanatory notes and extensive references to original sources. Electrolytic methods are described, but not potentiometric; 'gas analysis' is confined to the absorption of carbon dioxide for gravimetric purposes. The author strongly advocates the use of 'molar' solutions, abandoning the less specific term 'normal' in this connexion, but while admitting that the term 'millilitre' is desirable, continues the use of 'c.c.'. No text-book seems anxious to initiate this change.

We have read this book with considerable interest; it contains a large amount of useful information and is commended not only to the student but also to the chemist. B. A. ELLIS.

The Theory of Determinants, Matrices and Invariants. By Prof. H. W. Turnbull. Pp. xvi + 338. (London and Glasgow: Blackie and Son, Ltd., 1928.) 25*s.* net.

THIS excellent book gives a survey of a field which has come into great prominence during the present century for two quite different reasons. First, the theory of relativity has compelled physicists to extend their notions of space with the consequent necessity for formulating physical invariants appertaining to quaternary and higher forms. Secondly, the new mechanics has found a need for numbers obeying a non-commutative law of multiplication. Here the matrix representation was ready to hand. Prof. Turnbull has not made the mistake of attempting to develop the theory with an eye to its applications. Rather he has given a consistent and adequate account from the point of view of pure mathematics. Seven chapters on determinants and matrices are followed by a development of invariant theory mainly of quaternary and higher forms. Naturally in a subject of such vast extent a choice has to be made, but it will be found that the choice is extremely judicious.

The book is written in a delightfully lucid style and is admirably suited to the needs of those who wish to familiarise themselves with the mathematical concepts underlying the physical applications. To the student whose interests are purely mathematical, no better introduction could be desired. L. M. M.-T.

Jahresbericht über die wissenschaftliche Biologie: zugleich Bibliographisches Jahresregister der Berichte über die wissenschaftliche Biologie. Herausgegeben von Prof. Dr. Tibor Péterfi. Band 1: *Bericht über das Jahr 1926.* Pp. xii + 627. (Berlin: Julius Springer, 1928.) 69 gold marks.

THE editor states that the great majority of the titles in this "Jahresbericht" are taken from 1328 periodicals placed at his disposal by the publisher. The titles, each with proper bibliographical data, are arranged in sixteen sections, among which are methods, physical and chemical basis of vital processes, cytology and histology, morphology, metabolism, hormones, physiology of reproduction and development, heredity, ecology and systematics. The great majority of the titles relate to papers on animals. The index of authors and the alphabetical list of the sections of the work facilitate the rapid finding of the references to any author or subject. Some of the 7600 titles are repeated under different sections, so that the total number of titles printed is 11,500. A statistical analysis of the subjects dealt with is appended, which brings out the preponderance of works on comparative physiology (including the chemical and physical basis).

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Spectrum of Sunlit Aurora Rays as compared with the Spectrum of Lower Aurora in the Earth's Shadow.

ON several occasions, especially during the great aurora of Mar. 22–23, 1920, I have looked at sunlit auroral rays through a pocket spectroscope and always found the green auroral line very faint as compared with other strong lines in the blue and violet (Résultats des mesures photogrammétriques des aurores boréales, etc., p. 48, *Geof. Publik.*, vol. 4, No. 7). Wishing to obtain a more positive proof of this fact, I decided last winter to try to get spectrograms of these rays. I had already at my disposal some small kinema lenses of high light power and two glass prisms, one of which I had used with success to obtain prism objective photographs of aurora during my expedition to Bossekop in 1913. I was fortunate enough to get the most valuable assistance from Mr. Moxnes, engineer, attached to the physical institute of the University of Oslo. Two small spectrographs were built, one with greater dispersion but rather small light power, and the other with smaller dispersion but with very high light power.

The spectrographs were ready for use during the very interesting aurora of Mar. 15–16 last, mentioned in my recent communication to NATURE (June 8, p. 868). While Tveter, Wesöe, and I were occupied in taking photograms for determining the height and situation of the aurora, Moxnes used the spectrographs, pointing them towards all auroræ seen, especially towards all which were photographed.

Two quite successful spectrograms were obtained with the spectrograph of high light power:

(1) The first, exposed for about five hours, of all auroræ in the form of arcs, bands, rays, and curtains, during the first part of the night; the corresponding situations of the auroræ are seen in Fig. 1, to the right; they were relatively *low* and were situated in the *dark* part of the atmosphere (except one feeble ray without influence on the main result). The comparison spectrum was taken by Moxnes.

(2) The second one, exposed for about one hour, exclusively of all the *high sunlit aurora rays* just before dawn. The situation of those rays is seen to the left on the same diagram, Fig. 1, and was also given in my communication in NATURE of June 8. The spectrum with corresponding comparison spectrum was taken by Wesöe and Tveter; the exposure of the comparison spectrum was too long and therefore we have substituted a darker copy (Fig. 2, No. 2).

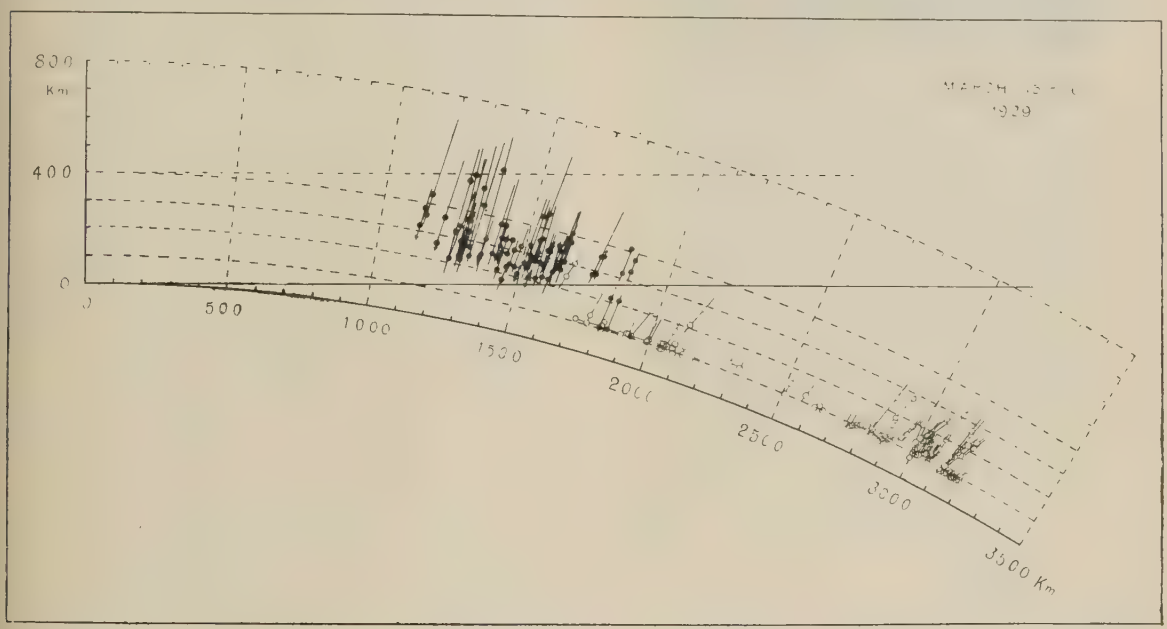

FIG. 1.—Situation of the aurora of Mar. 15–16, 1929, compared with the position of the earth's shadow. The figure represents a vertical section of the earth, and the tangent to the earth's surface is the boundary between the sunlit and dark atmosphere. The sunlit auroral rays are seen to the left, and each point calculated on them is marked by a black dot. The common aurora in the dark atmosphere is seen to the right, each point calculated being represented by a small circle.

On the night of April 16–17 last I received information from the State Telegraphic Department that earth currents were disturbing the telegraphic service. In consequence I warned all my aurora stations, and a long series of about seventy successful photograms from two, three, and four stations were secured. That night only high sunlit aurora rays occurred. Moxnes also took a spectrogram with the same spectrograph of high light power.

At my request Moxnes has here added the result of his measurements and calculations of the spectra. For details I must refer to a subsequent and more complete publication:

"The spectra were photographed on Sonia EW. plates from Herzog, Bremen, with a spectrograph of small dispersion but high light power. The light from a Hilger helium discharge lamp served as comparison spectrum.

"In the first experiment on Mar. 15–16 the slit was 0·15 mm. wide and gave rather broad lines. On April

16–17 the slit was 0·04 mm., and a spectrum with sharp lines was obtained. The spectra show the prominent lines of the aurora with wave-lengths 5577, 4278, 3914 A., and a diffuse band at 4700-4600 A.

"In spectrum No. 2, of the sunlit aurora rays of Mar. 16, the line 5577 is very much fainter than in spectrum No. 1 of the lower non-sunlit aurora of the same night, as compared with the other lines. This difference in relative intensity is very apparent when

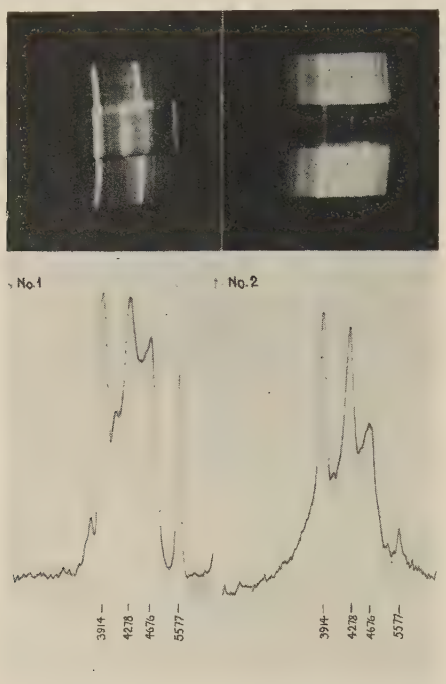

FIG. 2.—Spectrograms with corresponding photometric registrations made by a registering Moll photometer. No. 1 is of the common low aurora to the right in Fig. 1; No. 2 of the sunlit aurora rays to the left in the same figure.

the spectra are measured with a registering Moll photometer.

"The same character is shown by the spectrum of the sunlit aurora rays during the night of April 16–17."

It is thus seen from these observations that the green auroral line 5577, which is very strong for the common aurora in the earth's shadow, is very much fainter for the high sunlit aurora rays as compared with the lines of ionised nitrogen 4728 and 3914. This is in accordance with the blue and violet colour of these rays. No lines of helium or hydrogen seem to occur in the spectrum of those high rays.

These results are, however, to be considered only as preliminary. The researches will be continued next autumn.

CARL STØRMER.

Oslo.

Oyster Culture in Malaya.

As nothing is known about oyster culture in British Malaya, this note may be of interest. It is based on work done by myself while I was in charge of the Oyster Experiment Station started by the Federated Malay States Government at Kuala Kurau in Perak State. It is confined to general results, as the experiments only lasted for six months.

The locality selected for the experiment by the Fisheries Department was the mouth of the River Kurau, near Penang. Like most Malayan rivers, the Kurau courses along a soft, muddy bottom, which made it unsuitable for oyster culture under natural conditions. Two small rocky beds were, however, found in the deepest parts of the river (about seven fathoms at low tide), where oysters could be obtained, but only by employing a local diver.

All the usual methods of spat collecting were tried, but were practically unsuccessful. Crates of limed tiles were immersed and taken up and examined after a period of immersion of from three to four weeks. The tiles and the woodwork of these crates were literally smothered with barnacles, which grow very rapidly in Malayan waters, but in spite of this an average of about two spat per tile was collected. Other collecting methods employed included the letting down of ropes of brushwood, and of oyster shells enclosed in a wire-net bag, but these were no more successful than the crates, the former collecting scarcely any spat at all.

The question of relaying the spat now arose. So far as the river was concerned this proved to be an insoluble problem. A small bed (about 20 ft. × 20 ft.) by the banks of the river was selected because of its comparative firmness. This area was cultched with a lorry-load of stones and a lorry-load of mussel-shells, and the young oysters laid upon it. The rapidity with which mud was deposited soon made it obvious that the preparation of artificial beds was a futile measure. Putting the spat into small baskets let down into the river (they had to be frequently taken up and cleaned on account of the barnacles) proved more successful, but the method was merely an experimental one, and had no practical value, as adult oysters are extremely cheap in Malaya.

Another difficulty was the purification of the oysters. The river was heavily polluted with sewage, especially in the vicinity of the bed; at low tide pollution was sometimes so marked that it altered the *p*H of the water from alkalinity to 6·0 and even less. Sterilisation of the oysters in chlorinated water (the method approximated as closely to that in use at Conway as conditions permitted) proved unsuccessful. Unfortunately, the lack of equipment made bacteriological examinations at the station impossible, but samples of the chlorinated oysters were packed in a sterilised tin containing sterilised sea-water, and sent frequently to the Government Bacteriologist at Kuala Lumpur (a twelve hours' journey), with control samples of unsterilised oysters, both in sea-water and in sterile sea-water. It was found that the colonies of *B. coli* and other bacteria produced on the culture plates were generally too numerous to count, both in the chlorinated samples and the controls. As most of the Malayan rivers are similar to Kuala Kurau, this difficulty would have to be overcome by the installation of a proper chlorinating plant. The bacteriological results were extremely interesting, and it is hoped that the Government Bacteriologist will publish a short note on them.

Attempts at artificial oyster culture produced more promising results. For this purpose a solid wooden box was made, with an outflow through eighteen filter candles (the substance known as 'filtros' is more suitable, but I could not obtain it at the time). The outflow was collected in a two-inch false bottom below the candles and let out through a stopcock. The water was further aerated by mechanical agitation. In this box a few oysters were placed, and, just before the station closed down, a good fall of spat was obtained on tiles and on oyster-shells placed in the box. Sixteen large cement tanks fed with water from the river were also used for experiments. In four of

hem several hundred oysters were placed with collectors. Their outflow was very slow and was guarded with an elaborate structure of tiles, but in six months not a single spat was obtained. This may have been due to insufficient aeration and the absence of direct sunlight. These tanks were ideal, however, for relaying spat and young oysters, which thrived and grew rapidly in them.

In conclusion, I believe that oyster culture in Malaya on a commercial scale under natural conditions is not possible, though the Fisheries Department may help the native fishermen to supplement their incomes slightly by teaching them the general methods of oyster culture. Given sufficient capital and a good technical worker freed from restraint, the artificial culture of the Malayan oyster (kindly identified by Dr. B. Prashad as *Ostrea gryphoides* Schlotheim) may, however, be regarded as a sound commercial proposition. For in this work, few of the difficulties met with by artificial culturists in Europe and America occur. The climate of Malaya is warm and equable; the oysters breed throughout the year; their growth rate is extremely rapid (some spat about one month old were already 1¼ in. in length, while oysters three months old were more than 2 in. in length, and certain old specimens collected had exceeded a length of 1 ft.); the barnacle trouble can be removed by gross filtration of the incoming water; and special food can be easily supplied, as the algæ (which will be described shortly by Dr. K. Biswas) on which the Malayan oyster feeds can be readily cultured. As the Malayan oyster has a good flavour and artificially grown individuals would be superior to those found in the rivers (there is an anæmic industry at Bagan Datoh, Perak, and Muar, Johore), a demand for good oysters, at prices consistent with guaranteed purity, could easily be created by judicious advertising in the Malayan press.

Cedric Dover
(Sometime Ostreoculturist, F.M.S.).

Calcutta, June 18.

Isotope Effect in Spectra and Precise Atomic Weights.

It seems probable that many isotopes exist in amounts too small to fall within the experimental range of the mass spectrograph. This makes it desirable to seek some means of determining their atomic weights with sufficient accuracy to give reliable values of their packing effects. Two methods, of which the second appears generally applicable, will be discussed here.

In the case of oxygen isotope 17, the energy relationships accompanying the formation of this atom from a collision resulting in a combination of an alpha particle and a nitrogen nucleus with subsequent ejection of a proton, have been considered by a number of observers. Of these we will consider only the results of Kirsch (*Phys. Zeit.*, **26**, 457; 1925), which are given for alpha particles of the ranges 8·6, 7·0, 6·0, and 4·9 cm. respectively.

Kirsch, from a consideration of the initial energy of the alpha particle and the kinetic energies of the newly formed oxygen 17 and the ejected proton, finds that oxygen 17 contains 16×10^{-7}, 16×10^{-7}, 15×10^{-7}, and 15×10^{-7} ergs respectively of the energies originally possessed by the alpha particles listed above. From the relativity relation, energy $= mc^2$, the average of the four values leads to a mass of 0·0010, which is probably reliable to the last stated figure. Then the atomic weight of oxygen 17 is given by N + He + 0·0010 − H.

Birge (Suppl., *Phys. Rev.*, in press) has recently considered the available data on the atomic weights of several elements and has given values of the probable errors. The following values are given: $N = 14{\cdot}0083 \pm 0{\cdot}0008$, and $H = 1{\cdot}00777 \pm 0{\cdot}00002$. For He the value given in the table is 4·0022, but in a footnote this is corrected to the more reliable value $4{\cdot}0018 \pm 0{\cdot}0004$. Thus $O^{17} = 17{\cdot}0033 \pm 0{\cdot}0009$. This value is based on the assumption that the final state of oxygen 17, as considered by Kirsch, is the normal state of this nucleus. However, the total effect due to the energy is so small that an error in this regard would not be expected to have much influence.

In the case of oxygen 18, it has become evident that the band spectrum isotope effect can be used to give an extremely accurate value of the atomic weight.

The *A*-band of oxygen by which the existence of oxygen isotopes 17 and 18 were established (Giauque and Johnston, Nature, Mar. 2, p. 318, and June 1, p. 831; 1929; *J. Am. Chem. Soc.*, **51**, 1436; 1929) is quite insensitive to amounts of mass of the order of 0·001 gm., but can be used to establish the amount of the electronic isotope effect. This is expected to be negligible, but should be proved so. However, the *B*-band, which involves an increase of one unit of vibration during the excitation, is quite sensitive to the variation of mass. 0·001 gm. results in about 0·02 $cm.^{-1}$ in the isotopic displacement. The α-band, arising from an increase of two units of vibration, would be nearly twice as effective except that the diminishing intensity will increase the difficulty of measurement. The above method essentially involves the simultaneous use of two bands to solve for the two unknowns.

A personal communication from H. D. Babcock of Mount Wilson informs us that he has obtained excellent data on the *B*-band of the 18 − 16 oxygen molecule which will determine the atomic weight with high accuracy. It is evident that the above method is applicable to the isotopes of other elements when sufficiently accurate data become available. It is, however, limited to the intercomparison of the atomic weights of the various isotopes of a given element. From the atomic weight of an abundant isotope determined with the mass spectograph, the atomic weight of one present in very small amount may then be evaluated.

In order to utilise the isotope effect for this purpose, it will be desirable to use greater care in the theoretical treatment of the data than has previously been necessary in establishing the existence of the isotopic molecules. We have had the co-operation of R. T. Birge in this connexion, and a preliminary survey of the data indicates that it will be possible to obtain the atomic weight of oxygen 18 with a probable error in the neighbourhood of one part in twenty thousand. A joint publication will appear in the near future, based on measurements now in progress.

Zoological Nomenclature.

The undersigned has the honour to invite the attention of the zoological profession to the fact that Opinions 105 to 114 have been published by the Smithsonian Institution (*Smithsonian Miscellaneous Collections*, vol. 73, No. 6, pp. 1-26). The summaries read as follows:

Opinion 105. Dybowski's (1926) names of Crustacea suppressed.—Resolved: That all of the new names published in Dybowski's paper, "Synoptisches Verzeichnis mit kurzer Besprechung der Gattungen und Arten dieser Abteilung der Baikalflohkrebse"

(*Bul. internat. Acad. polonaise d. Sci. et. d. Lettres*, No. 1-2*b*, Jan.–Feb., pp. 1-77, 1926), are hereby suppressed, under suspension of the rules, on the ground that the application of the rules in accepting them "will clearly result in greater confusion than uniformity".

Opinion 106. The type of *Oestrus* Linn., 1758, is *O. ovis*.—The type of *Oestrus* Linn., 1758, is *O. ovis* (Art. 30*g*). Latreille's designation of *Oestrus equi* Fabr. as type of *Oestrus* is not valid (Art. 30*g*). The following five names of dipterous genera are hereby placed in the official list of generic names: *Cephenemyia* (type *trompe*), *Gasterophilus* (type *equi* of Clark, synonym of *intestinalis* de Geer), *Hypoderma* (type *bovis*), *Oedemagena* (type *tarandi*), and *Oestrus* (type *ovis*).

Opinion 107. *Echinocyamus pusillus* vs. *Echinocyamus minutus*.—The case of *Echinocyamus pusillus* vs. *Echinocyamus minutus* is subject to two diametrically opposed interpretations. On basis of the principle that a name in current use is not to be supplanted by an earlier but rarely adopted or an unadopted name unless the argument is unambiguous and unless the premises are not subject to difference of opinion, the Commission, because of the somewhat uncertain status of *minutus*, is of the opinion that *pusillus* 1776 should not be suppressed by *minutus* 1774.

Opinion 108. Suspension of rules for *Gazella* 1816.—Under suspension of the rules, *Gazella* Blainville, 1816, type species *Capra dorcas* Linn., 1758*a*, is adopted in preference to *Oryx*, and is hereby placed in the official list of generic names.

Opinion 109. Suspension of rules for *Hippotragus* 1846.—Under suspension of the rules (if need be), *Hippotragus* Sundevall, 1846, type species *Antilope leucophœa* Pallas, 1766, is adopted in preference to *Egocerus* Desmarest, 1822, and *Ozanna* Reichenbach, 1845 (not *Ægoceros* Pallas, 1811), and is hereby placed in the official list of generic names.

Opinion 110. Suspension of rules for *Lagidium* 1833.—Under suspension of the rules *Lagidium* Meyen, 1833, type species *Lagidium peruanum* Meyen, is adopted in preference to *Viscaccia* Oken, 1816, genotype '*Lepus chilensis* Molina', and is hereby placed in the official list of generic names.

Opinion 111. Suspension of rules for *Nycteris* 1795.—Under suspension of the rules *Nycteris* Cuvier and Geoffroy, 1795, type species *Vespertilio hispidus* Schreber, 1774, is adopted in preference to *Petalia* Gray, 1838, genotype *Nycteris javanica* Geoffroy, and is hereby placed in the official list of generic names.

Opinion 112. Suspension declined for *Manatus* 1772 vs. *Trichechus* 1758.—Suspension of the rules is declined for *Manatus* Brünnich, 1772, type species *Trichechus manatus* Linn., 1758*a*, type locality West Indies, vs. *Trichechus* Linn., 1758*a*, monotype *T. manatus*; accordingly the name *Trichechus* is to be used for the manatee instead of for the walrus. *Trichechus* Linn., 1758*a*, type *T. manatus*, is hereby placed in the official list of generic names.

Opinion 113. *Sarcoptes* Latreille, 1802, type *scabiei*, placed in official list.—*Sarcoptes* Latreille dates from 1802 instead of 1804 or 1806 as frequently quoted. It was originally monotypic, containing only *Acarus scabiei*. The 1810 type designation of *Acarus passerinus* is invalid under Article 30*c* and 30*ea*. The acceptance of *Acarus scabiei* as type species of *Acarus* is invalidated by Article 30*g*, according to which *Acarus siro* (syn. *farinæ*) is the type of *Acarus*. *Sarcoptes* Latr., 1802, mt. *scabiei*, is hereby placed in the official list of generic names.

Opinion 114. Under suspension, *Simia*, *Simia satyrus*, and *Pithecus* are suppressed. Under suspension of the rules the names *Simia*, *Simia satyrus*, and *Pithecus* are hereby suppressed on the ground that their retention under the rules will produce greater confusion than uniformity.

Statistics and Biological Research.

IN NATURE of July 20, "Student" propounds to me the problem of what *sort* of modification of my tables for the analysis of variance would be required to adapt that process to non-normal distributions. Since he and others evidently feel that a legitimate extension of my methods might be made along these lines, it may be worth while to point out the reasons for which, quite unusually, I disagree with his view.

The theoretical reasons may be made most clear by ignoring the limits of practical possibility, and supposing that an army of computers had extended the existing tables some two hundred fold, with the view of providing tests of significance for all distributions conforming to the Pearsonian system of frequency curves. The system of tests of significance so produced would then be exposed to criticism from three different angles.

(1) Following the lead of the reviewer in NATURE of June 8, p. 866, of my book, "Statistical Methods for Research Workers", it would be said that the new tables still needed 'correction' in order to include equally possible forms of distribution outside the Pearsonian system.

(2) A student of "Student" would surely point out that the parameters needed to enter the new tables must be calculated from the data available, and that allowance must be made for their sampling errors, by eliminating the Pearsonian parameters and replacing them by formulæ involving statistics only.

(3) A worker along my own lines would suggest that the particular statistics, means, and mean squares entering into these tests are only efficient for normal distributions, and that for Pearsonian curves quite other statistics are required, and not merely revised distributions of the familiar statistics appropriate to normal material.

The two last points could be met by dropping the Pearsonian system for one for which the moments are appropriate, when the way would lie open for the development of an analysis of the third and higher semi-invariants, bearing the same relation to the first attempt as the analysis of variance bears to some of the earlier calculus of correlations. An expert in cubic and biquadratic forms might here open out a new realm of statistical theory, for the application of which adequate data might in time be accumulated.

If the first objection is not ignored, more and more parameters may be introduced, but the patient investigator is still pursued by the analogues of these three criticisms; nor is there any doubt as to the limit of the process. It is not, as at first it might seem, the stultification of all statistical methods, but merely the abandonment of the theory of errors. Beyond all questions of metrical variates there are, largely undeveloped, a system of tests which depend only upon frequency and on order of magnitude. Examples exist in "Student's" writings, and in my own. They are free from all taint of normality, but are too insensitive to be very useful; still, their development would be of more interest than the programme of research first considered.

On the practical side there is little enough room for

anxiety, especially among biologists, who are used to checking the adequacy of their methods by control experiments. The difficulty of obtaining decisive results often flows from heterogeneity of material, often from causes of bias, often, too, from the difficulty of setting up an experiment in such a way as to obtain a valid estimate of error. I have never known difficulty to arise in biological work from imperfect normality of the variation, often though I have examined data for this particular cause of difficulty; nor is there, I believe, any case to the contrary in the literature. This is not to say that the deviation from "Student's" *t*-distribution found by Shewhart and Winters, for samples from rectangular and triangular distributions, may not have a real application in some technological work, but rather that such deviations have not been found, and are scarcely to be looked for, in biological research as ordinarily conducted.

Rothamsted Experimental Station,
Harpenden, July 26.

Nuclear Association in the Æcium of *Puccinia graminis*.

IN a letter to NATURE (July 23, 1927, p. 116) Craigie announced the discovery of heterothallism in the rust fungi. In a second letter (Nov. 26, 1927, p. 765) he showed that the æcial stage of *Puccinia graminis*—the parasite which causes the black stem rust disease of cereals—can be produced on the leaves of the common barberry at will simply by applying to the pycnia of a monosporidial pustule of one sex some of the pycniospore-containing nectar excreted from the pycnia of another monosporidial pustule of opposite sex.

A series of experiments on *Puccinia graminis*, recently made by me, has yielded some information as to the manner in which the change from the haploid to the diploid condition in this fungus is brought about.

The sporidia are uninucleate. In a pustule of monosporidial origin, the mycelium and the pycniospores produced by the mycelium are also uninucleate. In such a haploid pustule there appear, near the lower epidermis of the barberry leaf, numerous sterile wefts of mycelium. These wefts, which appear to be crescent-shaped in transverse sections of the leaf and are made up of hyphæ with uninucleate cells, are evidently haploid rudiments of æcial cups waiting to be stimulated into further developmental activity.

When nectar which contains pycniospores of one sex is applied to the pycnia of a monosporidial pustule of opposite sex, the wefts of hyphæ situated along the base of the pustule soon undergo a change from the haploid to the diploid condition. About 48 hours after the pycniospores have been applied, the nuclei at the base of each weft become enlarged. Neighbouring hyphæ then fuse in pairs in a manner similar to that described by Christman for *Phragmidium speciosum*, and two nuclei become associated in each fusion cell. The fusion cells, which initiate the diplophase, elongate and cut off chains of binucleate cells which later divide and thus form intercalary cells and æciospores. Sections through pustules fixed 65 hours after the application of pycniospores have shown young æcial cups with as many as four æciospores in several of the æciospore chains.

The part which the pycniospores play in bringing about æcial development is not yet completely understood. Some of the pycniospores have been observed to germinate, and, in one instance, the germ-tube from the spore had attained a length of 15 μ. In view of the fact that binucleate hyphæ are to be found only at the base of the æcium, it seems probable that, when pycniospores of one sex are applied to a pycnium of opposite sex, the pycniospores are stimulated to germinate and to produce haploid hyphæ which grow down to the hyphal wefts near the lower epidermis and there fuse with cells of opposite sex. The solution of the problem of tracing the hyphæ from the germinating pycniospores to the base of the æcium must await further investigation.

The Crystal Structure of Solid Nitrogen.

RECENT researches on the luminescence of solidified gases have shown that systems consisting of mixtures of nitrogen with inert gases give a great variety of oscillatory bands, which are intimately connected with the oscillations which the nitrogen atoms are able to perform in the crystalline state. As pointed out in previous papers, the determination of the crystal structures of these systems will be of fundamental importance for the interpretation of the oscillatory bands characteristic of the solid state.

Researches on the structure of solidified gases have already been taken up by W. H. Keesom and his collaborators at the Cryogenic Laboratory of Leyden (*Comm.*, Leyden, 178). For pure argon they find a face-centred lattice. In the case of nitrogen, which is the most important substance for our purpose, they merely state that they have obtained powder diagrams, which, however, are so complicated that they have not been able to interpret them by means of a definite unit cell and a corresponding crystal system.

As the oscillatory bands mostly originate from nitrogen, it is indeed the nitrogen structure which is of the greatest importance for the interpretation of the luminescence phenomena, and we have therefore also attacked the problem at the Physical Institute of Oslo. We obtained good powder diagrams with a conveniently constructed apparatus, and after having tried a number of crystal classes, we finally succeeded in showing that the spectrum could be interpreted by a unit cell belonging to the cubic system.

The side of the unit cube was found to be 5·65 A. units, and the density measurements of Dewar lead to the result that the unit cell contains 8 nitrogen atoms.

In these investigations I have been most ably assisted by Mr. Alf Maurstad, Mr. S. Stensholt, and Mr. E. Tønsberg.

Nature of Disease-Producing Viruses.

TWICE recently I have noticed in the columns of NATURE criticism of the hypothesis that disease-producing viruses are intermediate between molecule and living cell because no non-parasitic forms are known. Until viruses can be known other than by the effects of their parasitism, it would seem to be quite impossible to detect corresponding bodies that are not parasitic. I agree with the critics that if such bodies exist they may be much more numerous than the viruses, but until some method is devised by which the constituents of the viruses can be recognised, it would seem to be useless to look for them. For the hypothetical intermediate combining molecular structure, metabolism, and reproduction, I have been using the designation *vitamol*.

South Africa's Contribution to Prehistoric Archæology.[1]

By HENRY BALFOUR, F.R.S.

THE interest which is manifested in the study of the early chapters in the story of man's culture development is steadily increasing, not only in intensity but also in range, and there are now but few regions which remain totally unsearched for traces of early man and of his material activities. Interest becomes more *intense* as the scattered material is found more and more to belong to one huge complex problem, and it is realised that each scientifically collected item has a place in the cosmic mosaic, and may be the means of illuminating what has hitherto been obscure. The ever-increasing geographical *range* of this interest results largely from the discovery that from most parts of the world there may be collected data having a bearing upon these problems, and that it is profitable to search for traces of early man in almost any area which has ever been habitable.

Unfortunately the exceptional opportunities for study which have been offered by recent primitive peoples have largely been neglected, and the scientific value of close research into their material culture has usually not been recognised until it was already too late to reap the full benefit of the harvest. Civilisation has been more concerned with the extermination or rapid metamorphosis of primitive peoples and their industries than with their scientific investigation; and it is one of the tragedies of prehistory that so much of the invaluable and once accessible material should have been allowed to die away unstudied.

In the history of South African colonisation there may be noted such a failure to seize an opportunity of investigating fully a living primitive culture which might have thrown much light upon culture-details of long-vanished peoples elsewhere. The Bushmen and their kindred afforded an example of persistence of palæolithic conditions into recent times. Their culture was a purely Stone age culture, and they made and used stone implements of types many of which recall forms of implements which prevailed during the earlier section of the Late Palæolithic culture phase of western Europe and North Africa. The functions of the implements of the ancient series have been diagnosed so far as possible, and terms have been assigned to them, indicative of their presumed uses; but this is largely guesswork. Some degree of certainty, however, might have been reached had the living users of identical types of tools been closely studied, while the opportunity lasted, and had the details of manufacture and use of the various tool-types been placed on record.

It is too late for that record ever to be made complete and, from an archæological point of view, enlightening. Dispossessed of their old hunting-grounds, the miserable remnant of the once virile and widely dispersed Bushman race is rapidly passing away under environmental conditions so altered from those formerly enjoyed, that but little light can be thrown by the struggling survivors upon the true characteristics of Bushman culture. The old camp-sites, now deserted, must be investigated archæologically; and, in diagnosing the relics discovered, inference must take the place of direct observation.

Even that most striking feature of all, among Bushman relics, the rock-paintings and engravings, some of which are of very recent date, must be studied archæologically, on similar lines to those pursued in the interpretation of the strikingly similar artistic achievements of Aurignacian and Madeleinean man in France and Spain. How greatly would the interest of this prehistoric art in Europe have been enhanced if only a fuller comprehension of Bushman art had been arrived at by direct observation of its processes and functions. The artists have gone; this chapter in art-history is now closed, and there can be no period of *Renaissance*.

At the same time, while we must admit that the ethnological record is far weaker than it should be, through lack of scientific observation on the part of those pioneers who had opportunities of detailed study, we can note with great satisfaction the steady growth in South Africa of a keen interest in the archæological problems with which the country teems. The progressive development of local attention to the study of the Stone age in South Africa, the increasing desire for the establishment of a time-sequence of culture phases, coupled with the adoption of more precise scientific procedure in research, are features in the intellectual activity of the region the progress of which towards maturity I have myself to some extent been able directly to observe and follow.

My first visit to South Africa in 1899, exactly thirty years ago, revealed to me that, although a definite start had been made and collectors were in the field seeking for relics of the Stone age, this pastime was restricted to comparatively few enthusiasts, and the search was of a somewhat desultory nature, conducted without strict method or well-defined perspective outlook.

My second and third visits, in 1905 and in 1907, showed me that there were already many workers in the field, and that increasing attempts were being made to study the finds stratigraphically and to classify them in accordance with sequence dating. Still, the work of correlation was hampered by imperfect acquaintance with the results arrived at by European archæologists. This limitation led to some deductions which were scarcely justified by the facts.

In 1910 I again found myself in South Africa—by invitation of the South African Association. It was at once manifest that there was an increasing recognition of the importance of the geological associations of the earlier types of stone implements, as a means of establishing their relative antiquity and the ordered sequence of their succession. More serious attempts were being made to investigate

[1] From the presidential address to Section H (Anthropology) of the British Association, delivered at Johannesburg on Aug. 1.

ancient alluvial deposits and to record the particular strata from which implements were derived, and the depth within the strata. The archæological collections in the various museums were beginning to be grouped and arranged so as to tell a definite story—the story of the occupation of South Africa in early times by successive waves of immigrants, each wave introducing more or less distinctive culture elements. In this way the museums were not only attempting to furnish a summary of local archæological phenomena as interpreted up-to-date, but they were also offering suggestions as to the aims and objectives of future field-research, and indicating the nature of the problems awaiting solution.

This year it is my privilege to renew acquaintance with South Africa, the attractions of which, be they scenic, zoological, archæological, or ethnological, ever draw me with magnetic force. It is a very great pleasure to note the strides which have been taken since my last visit, nearly twenty years ago, towards unravelling the local archæological complex, and to note that this pursuit of knowledge is conducted on increasingly methodical and scientific lines.

It is manifest that the vast African area lying to the south of the Zambezi holds almost unparalleled wealth of archæological material. It appears as an inexhaustible mine of ancient relics. This is probably largely due to the successive waves of immigrant peoples having arrived in early times from the north. South Africa, though spacious, is a *cul-de-sac*, a land-terminus beyond which stretches the southern ocean, which arrested any further southward dispersal. We must picture the arrival, one after the other, of primitive peoples in various stages of culture advancement, and it is natural to assume that the order of their arrival in the far south is indicative of their general culture status. The more undeveloped peoples, less capable of defending their rights and of holding their own, yielded to the pressure of the more progressive peoples, before whose advance (due probably to similar causes) they gave way, eventually being forced down into the *cul-de-sac*, where abundance of game animals, no doubt, afforded compensatory attractions, and where they could establish and maintain themselves unmolested, until a new immigration brought a fresh racial stock into the region and renewed the clash of cultures.

During long ages, this sequence of irruptions of peoples inevitably induced a resultant congestion of heterogeneous ethnic elements, the weaker units continually giving way to the stronger, who, it may be reckoned, partly absorbed and partly exterminated the earlier occupants. The existing cultures must, at least, have been influenced and altered through contact with the new. Thus it is not difficult to see how, through a long sequence of immigrations into a region devoid of outlets, vast quantities of the more imperishable culture relics came to be accumulated in South Africa. It is also clear that the inevitable overlapping of cultures, coming into enforced contact in this Ultima Thule, tended to result in not only fusion but also confusion, and to bring about complex, hybrid industries, the parentage of which it is the aim of local archæologists to unravel.

The process of sorting out the data, and of classifying and evaluating the Stone age cultures represented in South Africa, is now proceeding apace, thanks to many keen research workers. Already several new names have been at least tentatively adopted for denoting various differentiated industries, which have been provisionally assigned their places in the chronological series.

This valuable archæological mine has as yet been only partially exploited, but its potential wealth is unquestioned; and, although prehistoric archæology must rank as a 'pure' science, and cannot be regarded as one which materially increases the *financial* welfare of the community, the finds which its pursuit brings to light must be regarded as a valuable asset to the country, worthy to be ranked with gold and diamonds and other commercially productive assets.

The great scientific importance of this valuable heritage imposes certain responsibilities upon the administration. Organisation in research is very desirable, and, although it is undesirable to curb the enthusiasm of untrained collectors, who may help very materially, it is to be hoped that, so far as possible, the field-work may be conducted under the advice and, when possible, the *surveillance* of properly trained and qualified archæologists, who may ensure that scientific methods will be pursued. This will render the finds collected more reliable as evidence, suitable for co-ordination, and capable of serving as material for building up the early human history of the region. The appointment of a carefully selected advisory committee would appear to be a practical measure, and might prevent much unprofitable work.
